Supporting Information

**ABSTRACT:** The nitramine-containing explosive RDX and the nitroester-containing explosive PETN are shown to be susceptible to photofragmentation upon exposure to sunlight. Model compounds containing nitroester and nitramine moieties are also shown to fragment upon exposure to UV irradiation. The products of this photofragmentation are reactive, electrophilic  $\text{NO}_x$  species, such as nitrous and nitric acid, nitric oxide, and nitrogen dioxide. *N,N*-Dimethylaniline is capable of being nitrated by the reactive, electrophilic  $\text{NO}_x$  photofragmentation products of RDX and PETN. A series of 9,9-disubstituted 9,10-dihydroacridines (DHAs) are synthesized from either *N*-phenylanthranilic acid methyl ester or a diphenylamine derivative and are similarly shown to be rapidly nitrated by the photofragmentation products of RDX and PETN. A new (turn-on) emission signal at 550 nm is observed upon nitration of DHAs due to the generation of fluorescent donor–acceptor chromophores. Using fluorescence spectroscopy, the presence of ca. 1.2 ng of RDX and 320 pg of PETN can be detected by DHA indicators in the solid state upon exposure to sunlight. The nitration of aromatic amines by the photofragmentation products of RDX and PETN is presented as a unique, highly selective detection mechanism for nitroester- and nitramine-containing explosives and DHAs are presented as inexpensive and impermanent fluorogenic indicators for the selective, standoff/remote identification of RDX and PETN.

## INTRODUCTION

Detecting hidden explosive devices in war zones and transportation hubs is an important pursuit. The three most commonly used highly energetic compounds in explosive formulations are 2,4,6-trinitrotoluene (TNT), 1,3,5-trinitrotriazinane (RDX), and pentaerythritol tetranitrate (PETN) (Figure 1). Numerous technologies are currently capable of detecting the energetic chemical components of explosive devices, including analytical spot tests,<sup>1</sup> fluorescent sensors using either small-molecule fluorophores<sup>2</sup> or fluorescent conjugated polymers,<sup>3</sup> chemiresistive sensors,<sup>4</sup> portable mass spectrometers,<sup>5</sup> and X-ray systems.<sup>6</sup> Each example listed has unique advantages and limitations. For instance, while X-ray systems are capable of detecting bulk hidden explosive devices and portable mass spectrometers are capable of identifying the exact chemical structures of suspect chemicals, the practical deployment and/or longevity of these hardware-intensive technologies in complex environments is nontrivial.<sup>5</sup> Fluorescent sensors are comparatively technology-unintensive, have desirably low detection limits, and are also capable of identifying (responding to) entire classes of molecules (such as nitroaromatics) or particular functional groups (*vide infra*).<sup>3</sup> Chemical spot tests can be more specific than fluorescent sensors but are not as sensitive and do not have the analytical advantages of an emissive signal, such as remote line-of-sight (stand-off) detection or prospects for

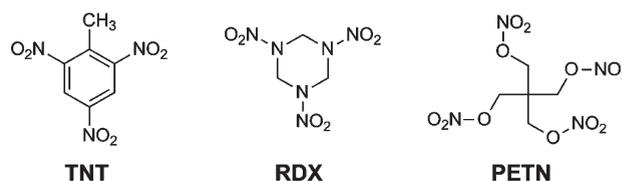

Figure 1. Structures of common high explosives.

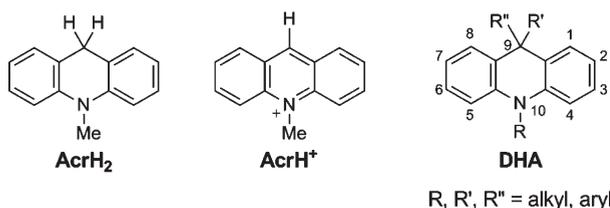

complex signal processing (i.e., fluorescence lifetimes, depolarization).

We previously reported a turn-on fluorescence chemosensing scheme based on the photoreaction between a hydride donor and either RDX or PETN, wherein the nitramine or nitroester component was photoreduced by 9,10-dihydroacridine ( $\text{AcrH}_2$ , Figure 2) or its metalated analogues.<sup>7</sup> The acridinium products ( $\text{AcrH}^+$ ) of this photoreaction had a high fluorescence quantum yield and resulted in a significant fluorescence turn-on signal in the presence of RDX and PETN.

While studying this photoreaction, we became interested in the photochemical stability of nitramine and nitroester compounds under ultraviolet (UV) irradiation. Nitroesters and nitramines

**Figure 2.** Structures of the hydride donor  $\text{AcrH}_2$ , its oxidation product  $\text{AcrH}^+$ , and the 9,9-disubstituted 9,10-dihydroacridines, **DHAs**, studied herein.

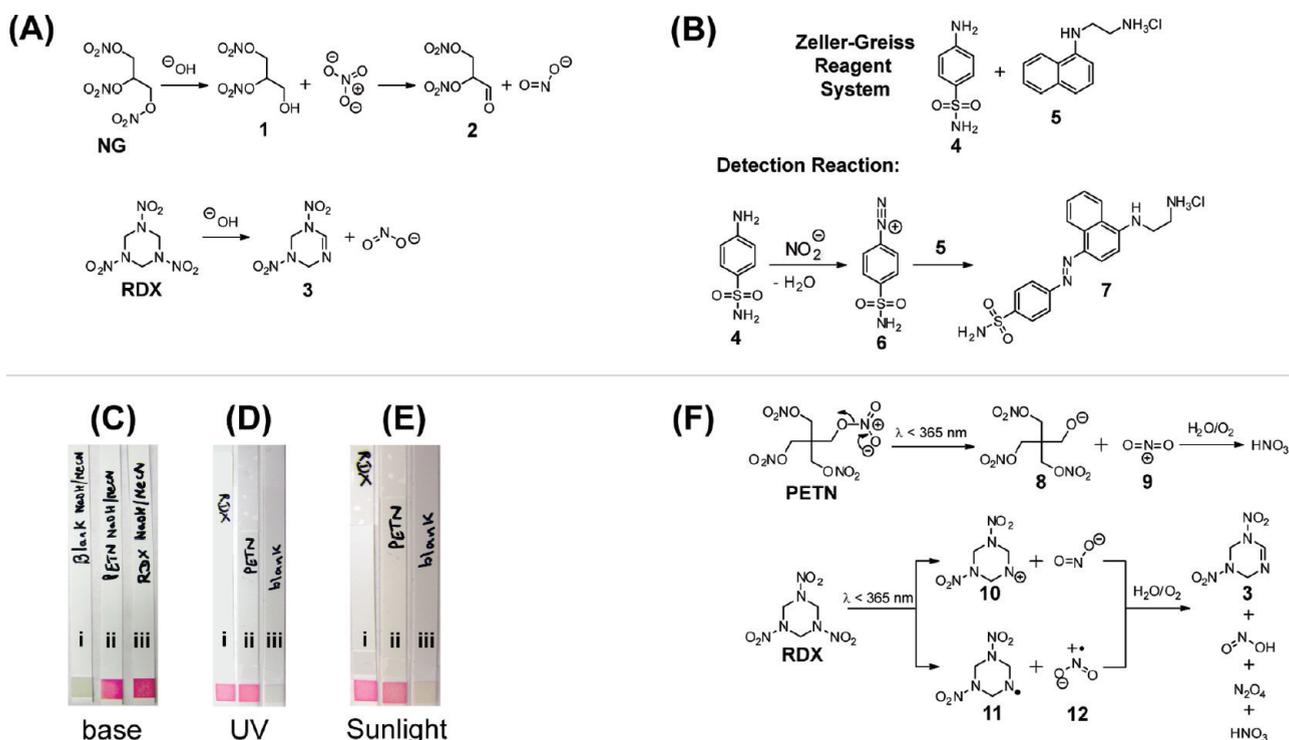

have been known to degrade under highly acidic or basic conditions and established spot tests for PETN and RDX detect these chemical degradation products as opposed to directly detecting intact PETN or RDX.<sup>1</sup> The base-promoted digestion of nitroglycerin (NG) has also been studied and is thought to evolve a mixture of nitrate and nitrite anions, among other degradation products (Scheme 1A).<sup>8</sup> Similarly, RDX is also known to decompose in basic media and produce nitrite ions (Scheme 1A).<sup>9</sup> The Greiss test<sup>10</sup> for nitrite ions can, therefore, be employed to confirm the evolution of nitrite upon base-promoted degradation of RDX and PETN. The chemistry behind the commercially available Greiss test (Scheme 1B) involves the reaction of sulfanilamide (4) with nitrite to form diazonium salt 6, which then reacts with an arylamine (5) to form a brightly

colored azo dye (7).<sup>11</sup> As seen in Scheme 1C, when nitrite test strips impregnated with the modified Greiss reagent were dipped into solutions of either RDX or PETN in 2:1 acetonitrile/1 M NaOH, a bright pink color evolved, indicating the presence of nitrite anions.

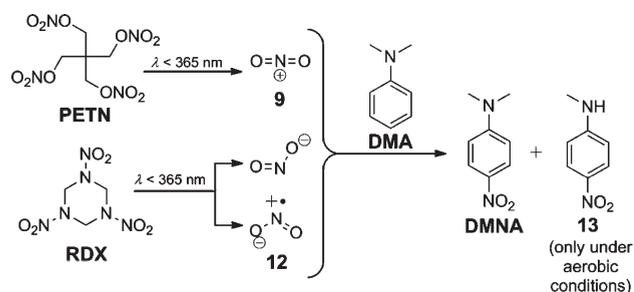

Interestingly, when the same nitrite test strips were dipped into base-free acetonitrile solutions of RDX or PETN, dried, and irradiated ( $\lambda = 254 \text{ nm}$ ), formation of the pink azo dye was also observed (Scheme 1D), suggesting the evolution of nitrite ions upon the photolysis of RDX and PETN. Photolysis at 313, 334, and 365 nm similarly resulted in a positive Greiss test; however, non-UV controls did not yield a pink color. Moreover, extended exposure (30 min) to polychromatic light from a solar simulator was also observed to photolyze RDX and PETN and yield a positive Greiss test (Scheme 1E).

The photolysis of nitroester- and nitramine-based energetic compounds under various conditions has been studied and found to produce a number of small-molecule degradation products, including nitrous and nitric acid, nitric oxide, nitrogen dioxide, formaldehyde, and ammonia.<sup>12</sup> The proposed photolytic degradation mechanisms for PETN and RDX are shown in Scheme 1F. In the case of PETN, it is hypothesized that heterolytic cleavage of the O-NO<sub>2</sub> bond initially produces an alkoxide (8) and a highly reactive nitronium ion (9) that rapidly forms nitric acid under ambient conditions.<sup>13</sup> For RDX, evidence of both the homolytic and heterolytic scission of the N-NO<sub>2</sub> bond of RDX

**Scheme 1.** (A) Degradation Mechanisms of Nitroesters and Nitramines in Basic Media. (B) Active Components and Detection Mechanism of the Zeller–Greiss Test for Nitrite Ions. (C) Nitrite Ion Test on Base-Degraded RDX and PETN.<sup>a</sup> (D) Nitrite Ion Test on Photolyzed RDX and PETN.<sup>b</sup> (E) Nitrite Ion Test on RDX and PETN Exposed to Sunlight.<sup>c</sup> (F) Proposed Photolytic Cleavage Pathway of Nitroesters and Nitramines and Select Photofragmentation Products

<sup>a</sup> Test strips were dipped into blank 2:1 MeCN/1 M NaOH (i) or 17 mg of PETN (ii) or 10 mg of RDX (iii) in 3 mL of 2:1 MeCN/1 M NaOH. <sup>b</sup> Test strips were dipped into (i) 10 mg of RDX or (ii) 15 mg of PETN in 3 mL of MeCN or (iii) neat MeCN and irradiated at 254 nm for 1 min. <sup>c</sup> Test strips were dipped into (i) 10 mg of RDX or (ii) 15 mg of PETN in 3 mL of MeCN or (iii) neat MeCN and irradiated with polychromatic light from a solar simulator for 30 min.

Scheme 2. Nitration of *N,N*-Dimethylaniline with the Photofragmentation Products of RDX and PETN

(to produce nitrogen dioxide (12) or nitrite, respectively) exists and the exact nature of the initial photoreaction is ambiguous.<sup>14,12d</sup> Nevertheless, it can be agreed that the proposed initial products of RDX and PETN photolysis are highly reactive, electrophilic  $\text{NO}_x$  species, which can conceivably convert sulfanilamide 4 to the diazonium cation 6 necessary to produce a positive result in the Zeller–Greiss test.

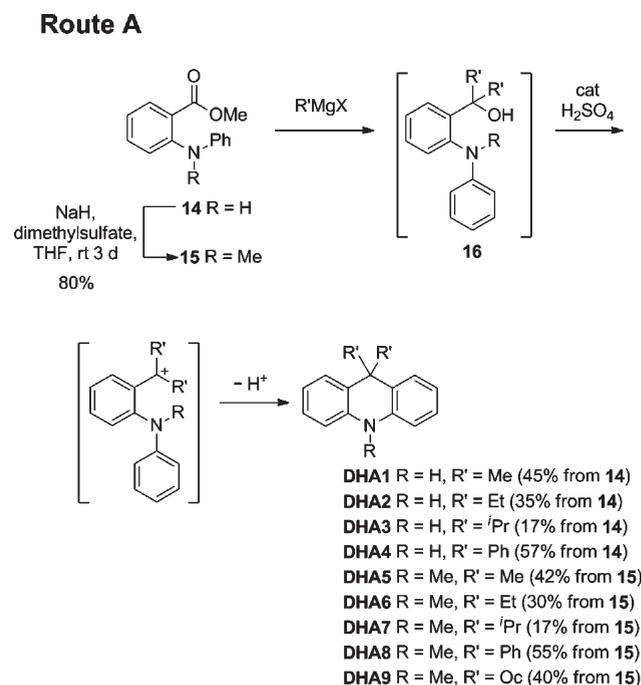

Unfortunately, the Greiss test or variations thereof cannot meet the detection requirements for RDX and PETN. First, simple standoff detection (detection at a distance) with colorimetric spot tests is not a viable possibility because of the difficulty in getting a clear optical signal returned from a purely absorptive process. Moreover, even with optimized reagent systems, the detection limit of the Greiss test is in the microgram regime,<sup>15</sup> which is not competitive with existing methods to detect RDX and PETN.

Herein, we propose instead a sensing scheme that is uniquely selective to the photolytic cleavage of nitroester and nitramine compounds through the formation of nitroaromatic products that provide a new fluorescence signal. The pro-fluorescent, or fluorogenic, indicators described herein are capable of efficiently reacting with the photofragments of RDX and PETN and constitute a new, highly selective and sensitive detection scheme for these explosives.

## RESULTS AND DISCUSSION

**Indicator Design.** Considering the electrophilic nature of the  $\text{NO}_x$  species generated by the photofragmentation of RDX and PETN and their resemblance to the active electrophiles in aromatic nitration reactions, we targeted reactions between electron-rich tertiary aromatic amines and the photofragments of RDX and PETN. It was found that photolysis ( $\lambda = 313$  nm) of a mixture of *N,N*-dimethylaniline (DMA) and 2 equiv of either RDX or PETN for 10 min in acetonitrile under anaerobic conditions afforded the formation of *N,N*-dimethyl-4-nitroaniline (DMNA) in 14% yield (GC yield). Higher yields of DMNA were obtained with longer photolysis times, and DMNA was formed in ca. 80% yield after 1 h. The photoreaction between DMA and either RDX or PETN under anaerobic conditions was observed to produce only a *single*, yellow-colored product (DMNA), and other side products were not evident by TLC or GC–MS analyses. The <sup>1</sup>H NMR, IR, and high-resolution mass spectra of the isolated yellow product exactly matched those obtained for an authentic commercial sample of DMNA. Conducting the photolysis under aerobic conditions resulted in partial demethylation of DMA<sup>16</sup> and yielded a mixture of DMNA and its demethylated analogue, *N*-methyl-4-nitroaniline (13) (see Scheme 2). Photolysis of DMA with ammonium nitrate

Scheme 3. Route A for the Synthesis of 9,9-Disubstituted 9,10-Dihydroacridines

was also found to produce DMNA, although longer photolysis times (>30 min) were required and greater amounts of demethylated side products were observed (most likely due to the presence of water or other nucleophiles in the solutions).

A distinct absorbance band centered at 400 nm was found to accompany the formation of the nitrated products under both aerobic and anaerobic conditions, which also matched the low energy charge-transfer band displayed by commercial DMNA. However, DMNA has a very low fluorescence quantum yield,<sup>17</sup> and therefore, a significant turn-on fluorescence signal is not generated upon reaction of DMA with the photofragmentation products of RDX and PETN.

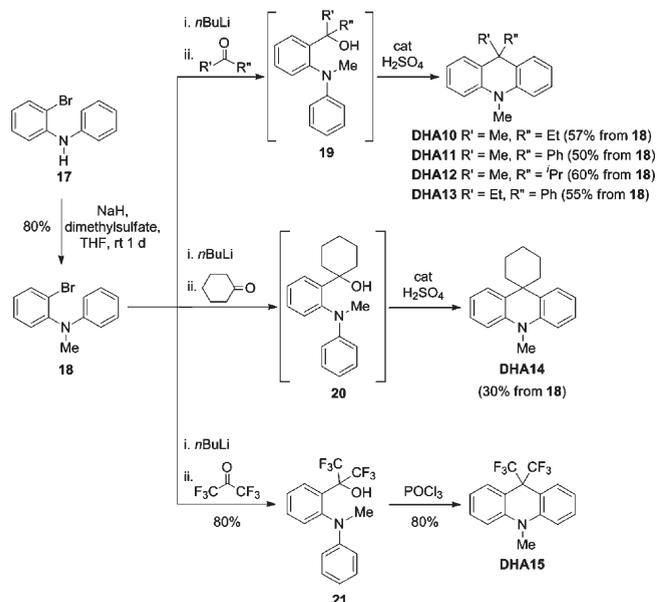

To probe the scope of the photonitration reaction, we investigated whether 9,9-dioctylfluorene, anisole, and 1,2-dimethoxybenzene could be nitrated by RDX and PETN. Extended photolysis (5 h) of a mixture of 9,9-dioctylfluorene and either RDX or PETN in 1:1 acetonitrile:THF at either 254, 313, 334, or 356 nm failed to generate any observable products and 9,9-dioctylfluorene was recovered in ca. 90% yield. Photolysis of anisole with RDX or PETN yielded only trace amounts of 4-nitroanisole (<1% GC yield) after 4 h. Photolysis of 1,2-dimethoxybenzene with either RDX or PETN yielded 1,2-dimethoxy-4-nitrobenzene in only ca. 8% yield after 2 h; moreover, this reaction did not proceed cleanly and numerous polar photoproducts were observed. Therefore, we concluded that anilines were the best candidates for a potential indicator.

To create fluorogenic indicators based on the facile nitration reaction between aromatic amines and the photofragmentation products of RDX and PETN, 9,9-disubstituted 9,10-dihydroacridines (DHAs, Figure 2) were targeted as chemosensors. We hypothesized that, upon nitration, the comparatively rigid DHAs would generate donor–acceptor chromophores possessing high fluorescence quantum yields.<sup>18</sup>

**Synthesis.** As shown in Schemes 3–5, a series of 9,9-disubstituted DHAs were synthesized, starting from either

## Scheme 4. Route B for the Synthesis of 9,9-Disubstituted DHAs

## Route B

*N*-phenylanthranilic acid methyl ester (routes A and C) or a diphenylamine derivative<sup>19</sup> (route B). DHAs were accessed by an acid-catalyzed cyclization of a tertiary alcohol intermediate (for example, structure 16). In route A (Scheme 3), intermediate 16 is accessed by a double 1,2-addition of an alkyl or aryl Grignard reagent to either *N*-phenylanthranilic acid methyl ester (14) or its *N*-methyl derivative (15); this strategy to synthesize DHAs has previously been reported.<sup>20</sup> In route B (Scheme 4), tertiary alcohol intermediates 19–21 are accessed from 1,2-addition of the aryllithium species derived from 18 to an appropriate ketone. This strategy was adopted to synthesize unsymmetric DHAs

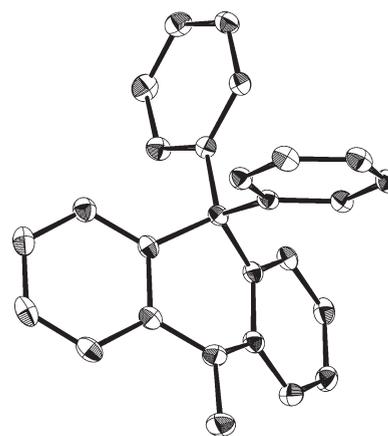

Figure 3. X-ray crystal structure of DHA8.

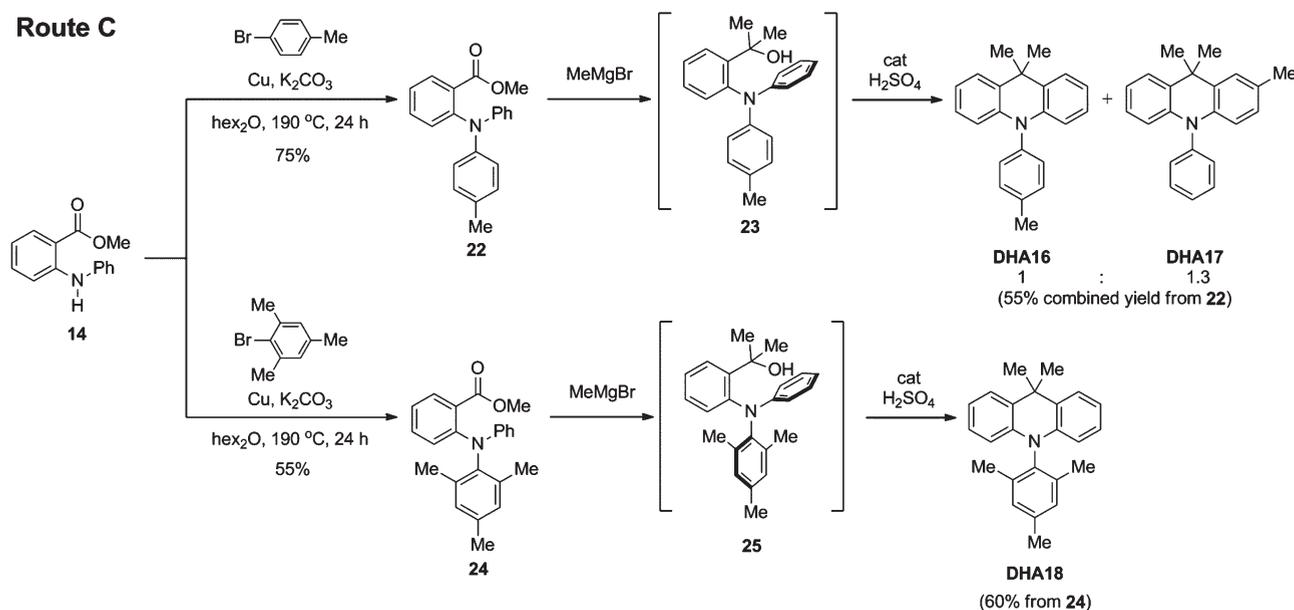

(DHA10–13) that have two different substituents at the 9-position, a spiro-DHA (DHA14), and a CF<sub>3</sub>-containing DHA (DHA15).

In all cases except one, adding a catalytic amount of concentrated sulfuric acid resulted in Friedel–Crafts reaction/cyclization of the respective tertiary alcohol intermediates to yield 9,9-disubstituted DHAs. As shown in Scheme 3, we posit that this transformation proceeds via formation of a carbocation. The X-ray crystal structure of DHA8 thus obtained is shown in Figure 3. The cyclization of compound 21 was uniquely challenging, as the use of neither strong acids, Lewis acids, nor thionyl chloride yielded DHA15.<sup>21</sup> However, it was found that refluxing a solution of 21 in POCl<sub>3</sub> produced DHA15 in high yield.

Lastly, route C was followed to synthesize *N*-aryl DHAs (Scheme 5). Copper-catalyzed *N*-arylation of 14 with 4-bromotoluene initially furnished 22, which was then reacted with 2.5 equiv of methylmagnesium bromide and catalytic concentrated sulfuric acid. Unfortunately, the Friedel–Crafts cyclization of intermediate 23 yielded a nearly statistical mixture of DHA16 and DHA17 (1:1.3 DHA16:DHA17), which could not be

Scheme 5. Route C for the Synthesis of *N*-Aryl DHAs

## Route C

acceptably separated by either column chromatography or recrystallization. Therefore, compound **24** was synthesized by copper-catalyzed *N*-arylation of **14** with 2-bromomesitylene and subsequently reacted with methylmagnesium bromide and sulfuric acid to access **DHA18**.

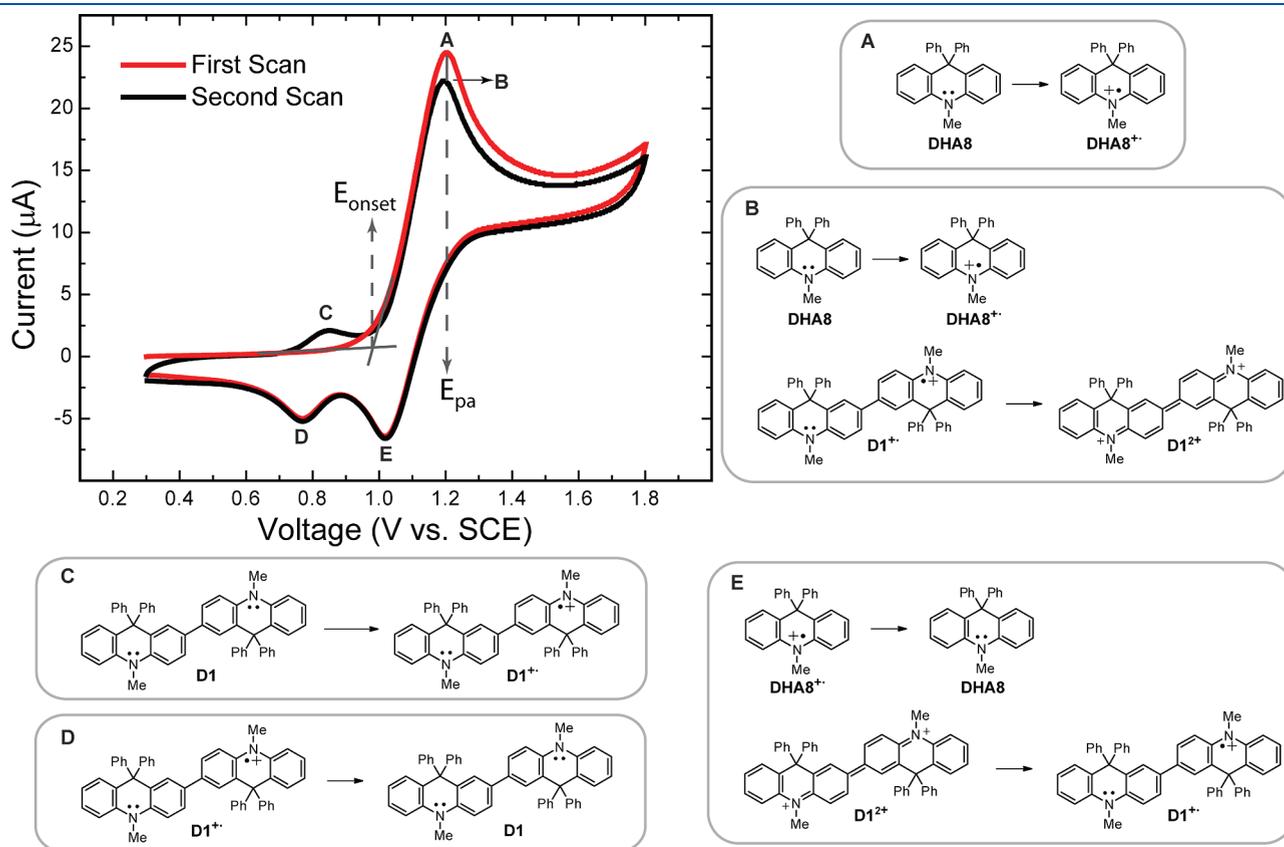

**Photophysics.** The optical properties of **DHA1–18** are summarized in the Supporting Information (Table S1). The DHAs reported herein displayed similar UV–vis absorption spectra, with absorption maxima around 290 nm. Additionally, **DHA1–18** generally displayed a single emission band centered at ca. 350 nm and were found to have similar fluorescence quantum yields and excited-state lifetimes.

**Electrochemistry.** Cyclic voltammograms (CVs) of select DHAs were recorded in  $\text{CH}_2\text{Cl}_2$  with tetrabutylammonium hexafluorophosphate ( $\text{TBAPF}_6$ ) as a supporting electrolyte and were found to reveal behavior suggestive of irreversible chemical transformations. The CV of **DHA8** is shown in Figure 4 as a representative example. The first anodic sweep resulted in a single oxidation peak at ca. 1.20 V vs SCE, which can be ascribed to the formation of the radical cation of **DHA8**. However, the corresponding cathodic sweep revealed two cathodic peaks, arising from the reduction of two different species in solution. Furthermore, a subsequent anodic sweep displayed two oxidation peaks. Such behavior has been previously observed for triphenylamine (**TPA**)<sup>22</sup> and is attributed to the rapid dimerization of **TPA** radical cations following oxidation; the electroactive **TPA** dimer thus formed leads to the growth of an additional anodic and cathodic peak after an initial anodic sweep. Based on assignments made for the CV of **TPA**,<sup>22</sup> the redox reactions responsible for the

individual anodic and cathodic peaks observed in the CV of **DHA8** were identified and are shown in Figure 3.

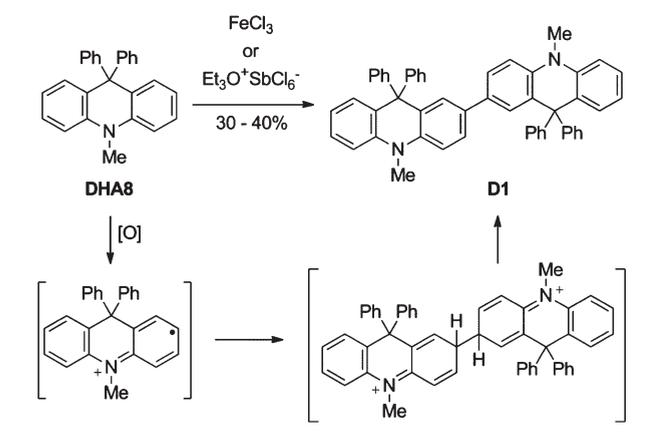

The dimerization of radical cations of **DHA8** in the electrochemical cell to form **D1** was confirmed by independently synthesizing **D1**. Oxidation of **DHA8** with  $\text{FeCl}_3$  or  $[\text{Et}_3\text{O}^+\text{SbCl}_6^-]$ <sup>23</sup> afforded **D1** in 30–40% yield (Scheme 6). This oxidation reaction was found to selectively yield the dimeric product (by TLC and crude  $^1\text{H}$  NMR analyses); moreover, we were able to recover the remaining, unreacted **DHA8** upon reaction workup. The use of hydrogen peroxide and *tert*-butyl-hydrogen peroxide was also investigated; however, surprisingly, **D1** was only formed in less than 5% yield with these reagents and **DHA8** was recovered in ca. 90% yield after reaction workup. Attempts to affect an oxidative polymerization of **DHA8** were not successful, and only **D1** was isolated. This observation can be explained by the fact that **D1**, once formed, can be oxidized to a stable, closed-shell dication (**D1**<sup>2+</sup>, see Figure 4) that cannot participate in subsequent radical coupling reactions to form polymers. Dimer **D1** is a faint-yellow compound that displays an absorption band centered at 457 nm and an emission band centered at 478 nm ( $\Phi$  0.20). The CV of **D1** (see Supporting Information, Figure S1) was found to match the second scan of the CV of **DHA8** (see Figure 4), thus confirming the aforementioned assignments for the anodic and cathodic peaks observed in the CV of **DHA8**.

The electrochemical behavior of **DHA8** was similar to that of the rest of the reported DHAs and also similar to the electrochemical behavior of **DMA**; i.e., the respective radical cations dimerized in the electrochemical cell after the first anodic sweep. The values for the first anodic peak potential ( $E_{\text{pa}}$ ) and onset

**Figure 4.** Cyclic voltammogram of **DHA8** (Pt button electrode, 0.1 M  $\text{TBAPF}_6$  in  $\text{CH}_2\text{Cl}_2$ , 100 mV/s). The redox reactions giving rise to each anodic (A–C) and cathodic (D and E) peak are shown, and the first anodic peak potential ( $E_{\text{pa}}$ ) and onset potential ( $E_{\text{onset}}$ ) for the first scan are labeled.

Scheme 6. Oxidative Dimerization of DHA8 To Form D1

potential ( $E_{\text{onset}}$ ) for the first scan of the CVs of select DHAs, DMA, and TPA are summarized in the Supporting Information (Table S2). In general, similar values of  $E_{\text{pa}}$  and  $E_{\text{onset}}$  were observed for most DHAs; however, the electron-deficient,  $\text{CF}_3$ -containing **DHA15** was an outlier and displayed significantly higher  $E_{\text{pa}}$  and  $E_{\text{onset}}$  values.

#### Reaction with RDX/PETN Photofragmentation Products.

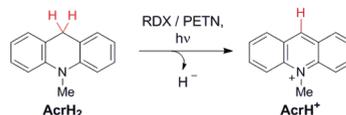

The photoreactions between **DHA1**–**18** and either RDX or PETN were initially investigated in acetonitrile solutions. In general, irradiating solutions containing **DHA1**–**18** and either RDX or PETN (which were initially colorless) at 313 nm under aerobic conditions lead to the evolution of a bright yellow/orange color after approximately 30 s to 5 min. Irradiating solutions of **DHA1**–**18** in the absence of either RDX or PETN did not result in the same bright yellow/orange color, although faint yellowing of the DHA solutions was noticed after greatly extended exposure (>60 min) to UV light under aerobic conditions.

The photolyses ( $\lambda = 313$  nm) of select DHAs with a stoichiometric amount of either RDX or PETN were conducted on a preparative scale in order to isolate and characterize the reaction products formed. In these studies, long irradiation times (generally 60 min) were employed to ensure complete reactant conversion. TLC and GC–MS analyses of crude reaction mixtures indicated that only a single, highly colored product was formed in all cases. The yellow-orange products from the reactions of **DHA1**, **DHA4**, and **DHA18** with either RDX or PETN were isolated by flash column chromatography and identified to be the mononitrated structures (**26**, **28**, and **30**, respectively) shown in Scheme 7 by their  $^1\text{H}$  NMR, FT-IR, and high-resolution mass spectra (see the Supporting Information). Compounds **26**, **28**, and **30** were isolated in 70–80% yield after column chromatography, along with ca. 10–15% of unreacted **DHA1**, **DHA4**, or **DHA18**. Similarly, **DHA5** and **DHA8** were confirmed to produce **27** and **29**, respectively, in approximately 70% yield (GC yield) upon photolysis with RDX or PETN (30 min). Additionally, **DHA1** and **DHA4** were independently nitrated under mild conditions using  $\text{SiO}_2/\text{HNO}_3$ ,<sup>24</sup> and the products thus obtained were found to match those isolated from the photoreactions of **DHA1** and **DHA4** with RDX/PETN.

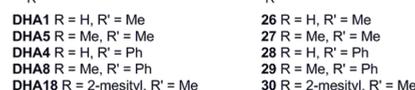

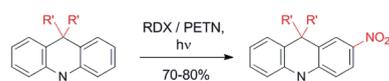

The photoreaction of **DHA2** with either RDX or PETN yielded the nitrated product **31**; however, compound **33** was also isolated from the reaction mixture (Scheme 7). The yield of **33** was found to be somewhat dependent on the concentration of

Scheme 7. Photoreactions of Various 9,10-Dihydroacridines with RDX and PETN<sup>a</sup>

Photoreduction of RDX/PETN by Hydride Donors:

Nitration of Aromatic Amines by the Photodegradation Products of RDX/PETN:

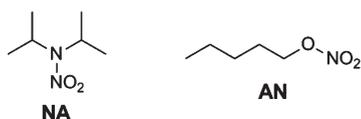

<sup>a</sup> The photoreduction of RDX/PETN by AcrH<sub>2</sub> has been previously reported.<sup>7</sup>

**DHA2**, with a higher amount of **33** over **31** observed in dilute solutions. The yield of **33** was also higher relative to that of **31** when the photolysis of **DHA2** and RDX/PETN was conducted in slightly wet acetonitrile. Compounds **31** and **33** were generally isolated in 80% combined yield after flash column chromatography of the photoreactions between **DHA2** and either RDX or PETN. Furthermore, **DHA6** was confirmed to produce **32** and **34** (by GC–MS analysis) upon photolysis in the presence of RDX/PETN. We hypothesize that **33** and **34** are formed as a result of either  $\text{H}^\bullet$  or hydride abstraction reactions between **DHA2** or **DHA6** and the photodegradation products of RDX and PETN. However, we are currently unsure as to the origins of the concentration dependence of the yield of **33**.

GC–MS analyses of the photoreactions between the remaining DHAs (**DHA3**, **DHA7**, **DHA9**, **DHA10**–**17**) and either RDX or PETN similarly revealed the formation of mononitrated derivatives of the respective DHAs.

**Other Nitroesters and Nitramines.** The photoreactions between **DHA1**–**18** and either a model nitramine or nitroester compound—*N,N*-diisopropyl nitramine (**NA**) and amyl nitrate (**AN**), respectively (Figure 5)—were also investigated. The reaction products observed upon photolysis ( $\lambda = 313$  nm) of mixtures of **DHA1**–**18** and either **NA** or **AN** were identical (as established by TLC and GC–MS analyses) to the aforementioned nitrated products observed with RDX and PETN. However, the observed yields (GC yields) of nitrated DHAs were significantly lower with **NA/AN**, as compared to RDX/PETN. For example, whereas **26** was formed in 75% yield upon photolysis with either RDX or PETN for 30 min, the photolysis of **DHA1** with **NA** or **AN** afforded **26** in only 30% yield under identical reaction conditions. Therefore, it can be tentatively inferred that RDX and PETN are more susceptible to photolytic cleavage than their respective model compounds.

**Figure 5.** Structures of a model nitramine, *N,N*-diisopropylnitramine (NA), and a model nitroester, amyl nitrate (AN).

**Differences in DHA Reaction Mechanisms.** As shown in Scheme 7, it is interesting to note the difference in photochemical reaction mechanisms between various 9,10-dihydroacridines. As previously reported,<sup>7</sup> *N*-methyl-9,10-dihydroacridine (**AcrH<sub>2</sub>**) participates in a hydride transfer reaction with either RDX, PETN, NA, or AN. Dialkylation or diarylation of the 9-position of **AcrH<sub>2</sub>** effectively nullifies its ability to donate a hydride ion and promotes the photonitration reaction detailed herein.

**Light Sources.** Importantly, precise timing and sophisticated, high-intensity light sources were not found to be necessary to effect the reaction between **DHA1-18** and the degradation products of either RDX or PETN. Simply exposing a mixture of **DHA1-18** and RDX/PETN to polychromatic light from a solar simulator effected the photolytic cleavage of RDX/PETN and subsequent formation of mononitrated DHAs. For example, compounds **26** and **28** could both be isolated in 75% yield (after flash column chromatography) after a mixture of RDX or PETN and **DHA1** or **DHA4**, respectively, in acetonitrile were exposed to simulated sunlight for 45 min. The yields of compounds **26** and **28** thus obtained are similar to those reported earlier for photolysis at 313 nm.

**Other NO<sub>x</sub> Sources.** The (photo)reactions of **DHA1-18** with sodium nitrite, potassium nitrate, and NO were also investigated to judge the limitations of using **DHA1-18** as stand-off indicators for RDX/PETN. Exposing a mixture of either **DHA1**, **DHA5**, **DHA4**, or **DHA8** and excess sodium nitrite in 2:1 acetonitrile/water to simulated sunlight for 2 h did not result in significant nitration of these DHAs (<1% GC yields of **26–29** were generally observed). However, upon addition of 100  $\mu$ L acetic acid to the same reaction mixtures, compounds **26–29** were formed in approximately 8% yield in the absence of light. Protonating nitrite salts generates nitrous acid, which is known to decompose and form HNO<sub>3</sub> (among other species), which most likely nitrated the DHAs in this case.

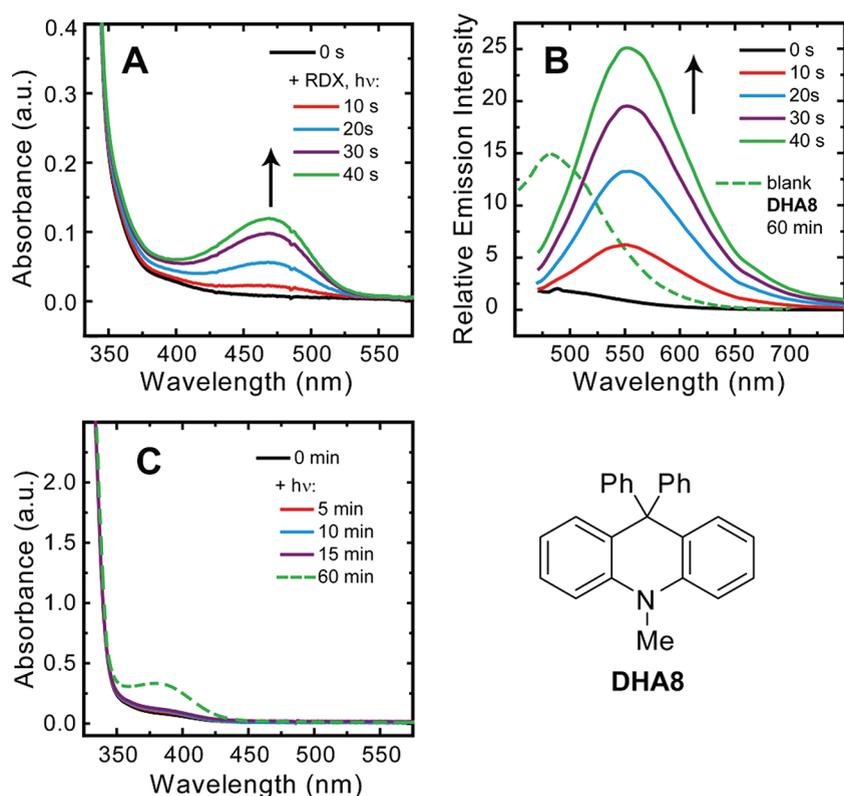

The addition of a large excess of monomeric NO gas to dry, oxygen-free solutions of the aforementioned DHAs failed to generate the characteristic yellow-orange color of **26–29**;

**Figure 6.** Absorption (A) and emission (B,  $\lambda_{\text{ex}} = 415$  nm) profiles of the photoreaction of **DHA5** with RDX in acetonitrile upon irradiation at 313 nm. [**DHA5**] =  $1.3 \times 10^{-4}$  M. [**RDX**] =  $5.4 \times 10^{-5}$  M. Identical profiles are observed for the photoreactions of **DHA5** with PETN. The presence or absence of oxygen similarly does not affect the observed absorption and emission profiles. The absorption profile for the extended irradiation of a blank, aerated solution of **DHA5** is also shown (C).

**Figure 7.** (A) Absorption profile of the photoreaction of **DHAS** and RDX in acetonitrile upon exposure to broad-band light from a solar simulator.  $[\text{DHAS}] = 1.3 \times 10^{-4} \text{ M}$ .  $[\text{RDX}] = 5.4 \times 10^{-5} \text{ M}$ . (B) The rate of formation of the 408 nm absorbance peak in the presence of RDX upon exposure to either simulated sunlight ( $120 \text{ mW/cm}^2$ ) or monochromatic 313 nm light ( $10 \text{ mW/cm}^2$ ).

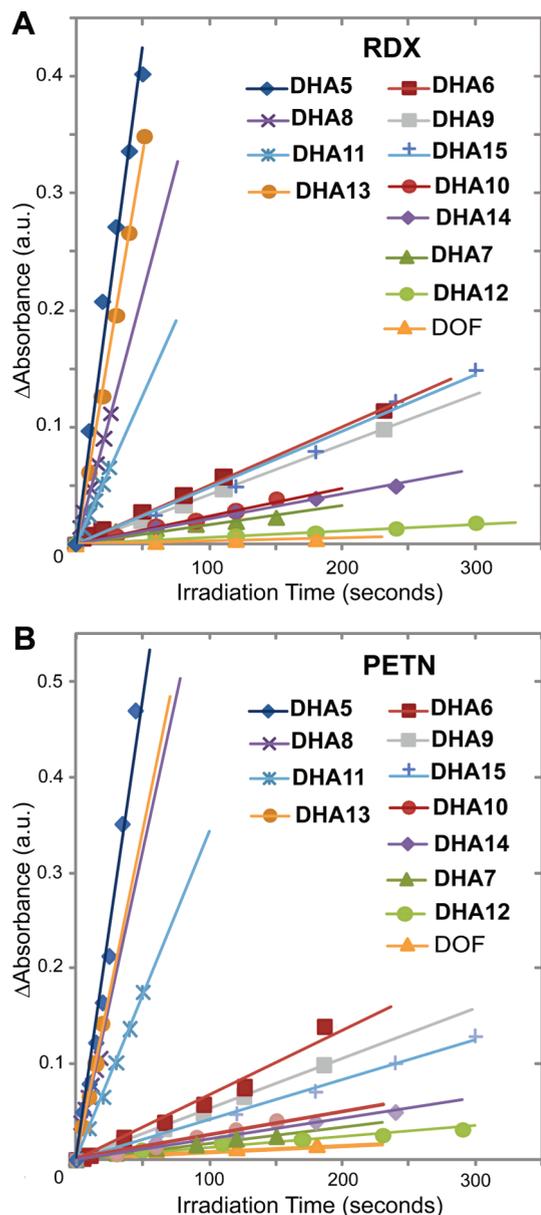

**Figure 8.** Absorption (A) and emission (B,  $\lambda_{\text{ex}} = 470 \text{ nm}$ ) profiles of the photoreaction of **DHAS** with RDX in acetonitrile upon exposure to simulated sunlight.  $[\text{DHAS}] = 1.3 \times 10^{-4} \text{ M}$ .  $[\text{RDX}] = 5.4 \times 10^{-5} \text{ M}$ . The dashed green line depicts the emission spectrum obtained for a blank solution of **DHAS** after irradiation under either aerobic or anaerobic conditions for 60 min. The absorption profile for the irradiation of a blank, aerated solution of **DHAS** is also shown (C); the same profile is also obtained for oxygen-free solutions of **DHAS**.

however, upon introduction of oxygen to these solutions, the nitrated DHAs were observed to be formed by eye (in the absence of light). Subsequent GC–MS analyses confirmed that **26–29** were formed in ca. 20% yield. Once again, NO is known to form nitrogen dioxide upon exposure to oxygen, which most likely resulted in nitration of the DHAs.

Mixtures of **DHA1**, **DHAS**, **DHA4**, or **DHA8** and a large excess of potassium nitrate in 2:1 acetonitrile/water did not immediately result in nitration. If allowed to stand for 24 h, **26–29**, along with multiply nitrated derivatives of the aforementioned DHAs, were formed in less than 5% combined yield (GC yield). Adding acetic acid to **DHA/KNO<sub>3</sub>** mixtures resulted

in the formation of multiply nitrated DHAs, with 2,7-dinitro DHAs being the major products. Exposing mixtures of either **DHA1**, **DHAS**, **DHA4**, or **DHA8** and a large excess of potassium nitrate in 2:1 acetonitrile/water to simulated sunlight for 60 min similarly yielded multiply nitrated derivatives of these DHAs in approximately 20% combined yield. Stoichiometric or substoichiometric amounts of potassium nitrate or shorter irradiation times failed to generate observable quantities of nitrated DHAs.

**Optical Properties of Nitrated DHAs.** The photophysical properties of select nitrated DHAs, which were either isolated from the photolysis reactions between DHAs and RDX/PETN or synthesized by nitrating an appropriate DHA, are listed in

**Figure 9.** Effect of the substituents at the 9-position of DHAs on their photoreactions with RDX and PETN. Shown are the rates of evolution of the absorbance peak at 410 nm (470 nm for DHA8) for the photoreactions between DHA5-15 and (A) RDX or (B) PETN. DOF is 9,9-dioctylfluorene, which was used as a negative control.

Table 1. In general, the nitrated DHAs displayed similar absorbance bands as DMNA, with the lowest energy bands centered at ca. 400 nm. Additionally, emission bands centered at ca. 540 nm were observed for all isolated mononitrated DHAs. The fluorescence quantum yields of the compounds listed in Table 1 were found to be solvent dependent, with the lowest quantum yields observed in acetonitrile.<sup>25</sup> Moreover, compounds 26, 28, 30, and 31 were found to display significant emission in the solid state (in cellulose acetate films containing 10 wt % of the appropriate compound).

**Optical Characterization of Indicator Response.** The absorption and emission profiles for the reaction between DHA5 and RDX under aerobic conditions are shown in Figure 6. An

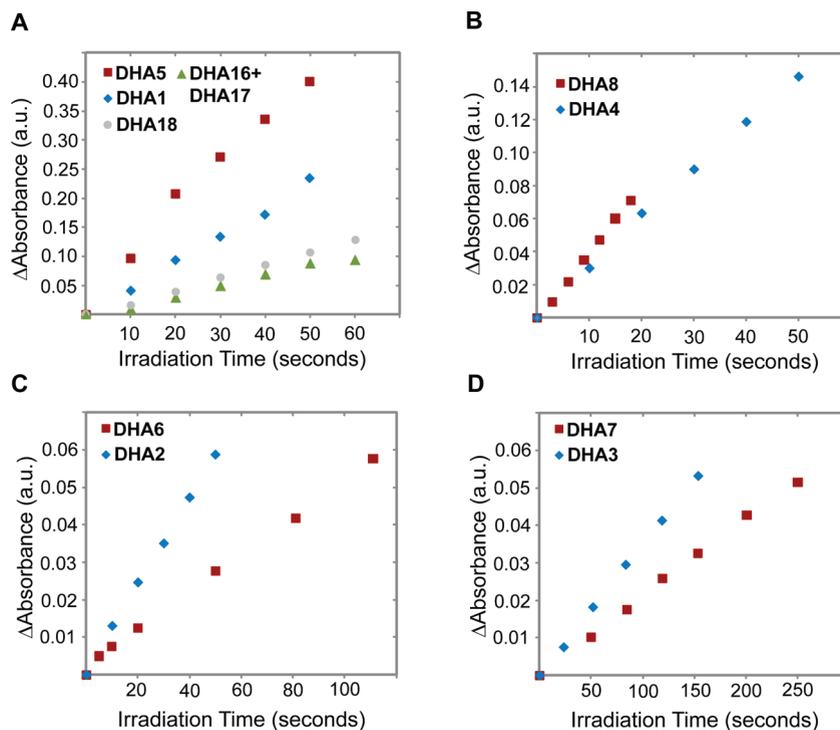

absorption band centered at ca. 408 nm was observed to evolve when DHA5 is photolyzed ( $\lambda$  313 nm) with RDX, which corresponds to the formation of 27. An emission band at approximately 540 nm concomitantly evolved, which can be assigned to emission from 27 based on the emission profile recorded for its *N*-H analog 26. A ca. 27-fold increase in the emission intensity at 540 nm was generated after 2 min of UV irradiation. Exactly similar absorption and emission profiles were obtained for the photoreaction between DHA5 and PETN. Moreover, the presence or absence of oxygen did not noticeably change the observed optical response.

Photolysis of DHA5 under aerobic conditions in the absence of RDX/PETN failed to generate a distinct absorbance band at 408 nm. Surprisingly, electron-rich DHA5 was found to be relatively photostable: 30 min of continuous UV irradiation did not result in a noticeable change in the absorption spectrum of DHA5 (Figure 6C), and its emission peak at 355 nm was found to be bleached by only 10%. Further UV irradiation eventually lead to slight yellowing of DHA5 solutions, and poorly defined absorbance peaks at 356 nm and ca. 440 nm appeared in the absorption spectrum after 2 h of continuous UV irradiation under air (Figure 6C). These new absorption peaks most likely correspond to the formation of radical cations, *N*-demethylated species, and/or *N*-oxide derivatives of DHA5. Notably, though, a significant portion of this photolyzed DHA5 solution remained unoxidized after 2 h, and therefore, the subsequent addition of RDX or PETN nonetheless lead to evolution of a 408 absorbance peak and 540 nm emission peak (5-fold emission turn-on) after a 20 s exposure to 313 nm light.

As seen in Figure 7, exposing a mixture of DHA5 and RDX to broad-band light from a solar simulator lead to the evolution of the same 408 nm peak observed with irradiation at 313 nm. The rate of formation of the 408 nm peak upon exposure to simulated sunlight also matched that observed upon exposure to monochromatic 313 nm light from a xenon arc lamp (Figure 7B). Therefore, simulated sunlight was preferentially used as the light source in subsequent studies to prove that the DHAs can function as technology-unintensive, fluorogenic indicators for RDX/PETN under ambient sunlight.

DHA6 behaved similar to DHA5 in terms of its optical response (the absorption and emission profiles for the reaction between DHA6 and PETN upon exposure to simulated sunlight are shown in the Supporting Information, Figure S2). Specifically, an absorbance peak at 409 nm evolved in the presence of either RDX or PETN, accompanied with evolution of an emission band at 540 nm. The presence or absence of oxygen did not affect the observed optical response to RDX/PETN. DHA6 was also found to be relatively photostable, with no change in its absorption spectrum and a 5% bleaching of its emission band at 382 nm observed after 30 min of continuous exposure to sunlight. The only significant difference between DHA5 and DHA6 was the rate of formation of the 409 nm/540 nm absorption/emission peaks. DHA5 was found to yield a turn-on signal approximately three times faster than DHA6. We hypothesize that this comparatively slow response is because DHA6 forms a mixture of 32 and 34 upon reacting with RDX/PETN (see Scheme 7).

The optical response of DHA18 to either RDX or PETN was also similar to that of DHA5 (see the Supporting Information, Figure S3). An absorbance band at 413 nm and an emission peak at 550 nm evolved upon exposure to simulated sunlight in the presence of either RDX or PETN. DHA18 was also relatively

**Figure 10.** Effect of the *N*-substituent of DHAs on their photoreactions with RDX. Shown are the rates of evolution of the absorbance peak at 410 nm (470 nm for **DHA8**) for the photoreactions between various DHAs and RDX.

photostable, with no change in its absorption spectrum and a 5% bleach of its emission band at 371 nm observed after continuous exposure to simulated sunlight for 30 min. The rate of photo-reaction of **DHA18** with RDX/PETN was slower than that of **DHA5** but faster than that of **DHA6**.

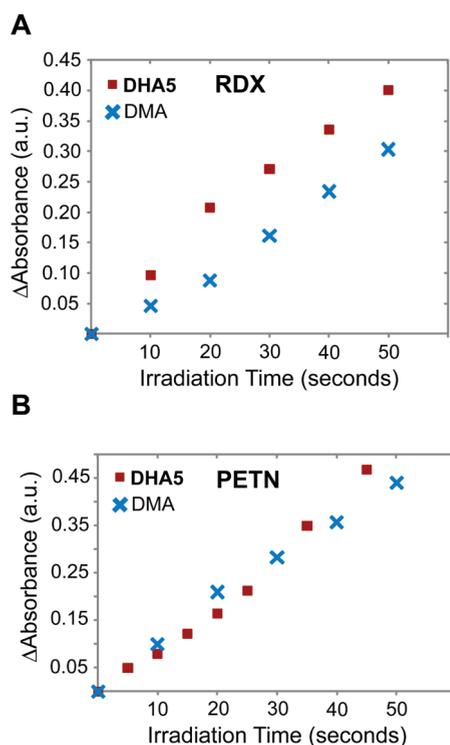

9,9-Diphenyl-substituted **DHA8** differed slightly from the other DHAs explored in this work, as an absorbance band centered at 470 nm, as opposed to ca. 410 nm, evolved during its photoreaction with either RDX or PETN (Figure 8). On the basis of the accompanying GC–MS analyses, this absorbance band could be assigned to the formation of **29**. An emission band at 550 nm was also observed to evolve concomitantly. An approximately 25-fold increase in the emission intensity at 550 nm was generated in the presence of either RDX or PETN upon exposure to simulated sunlight for 40 s. The rates of reaction of **DHA5** and **DHA8** with RDX/PETN were approximately similar.

Unlike **DHA5**, **DHA6**, and **DHA18**, exposing solutions of **DHA8** to sunlight (or monochromatic UV light) in either the presence or absence of oxygen lead to the formation of a distinct absorbance band at 380 nm, with an accompanying emission band centered at 478 nm. The same photoreactivity was also observed for other DHAs that contained at least one phenyl substituent in the 9-position (**DHA4**, **DHA11**, and **DHA13**). Since these absorption/emission bands were observed to evolve even in the absence of oxygen, they are most likely not generated by simple photooxidation products of **DHA8**. Moreover, the evolution of the absorbance band at 380 nm cannot be ascribed to a photodimerization event, as the product of such a reaction, **D1** (Scheme 6), has an absorption maximum of 457 nm. We are currently unsure as to the origin of the photoproduct responsible for the 380 nm/478 nm absorption/emission peak but suspect that a photocyclization reaction occurs in DHAs with at least one phenyl substituent in the 9-position. Nevertheless, for the purposes

of this work, it can be seen in Figure 8 that the competing photoreaction in blank solutions of **DHA8** (dashed green line) is slower than the photonitration of **DHA8** in the presence of RDX/PETN and an emission peak at 550 nm is clearly generated by these explosives in under 10 s.

**Reaction Kinetics.** The most significant difference between the DHAs reported in this work involved the rate of formation of the nitrated photoproducts upon reaction with RDX or PETN. By following the evolution of the characteristic low-energy charge transfer band (centered at ca. 400 nm) of the nitrated DHAs with irradiation time, we were able to identify differences in the reactivities of **DHA1–18** (Figures 9 and 10). As can be seen in Figure 9, the substituents at the 9-position of DHAs significantly affected their reactivities. DHAs with at least one methyl or phenyl substituent at the 9-position were rapidly nitrated in the presence of RDX or PETN. DHAs with alkyl (other than methyl) substituents at the 9-position displayed relatively slower rates of nitration, with isopropyl substituents leading to the slowest reaction rates. Replacing the 9-methyl substituents with trifluoromethyl moieties also retarded the reaction rate. Nominally faster reaction rates were generally observed with PETN over RDX for all DHAs. 9,9-Dioctylfluorene was used as a negative control for these studies, and in all cases, the DHAs reported in this work yielded a significant absorption signal at 400 nm over background.

The nature of the *N*-substituent was also found to affect the rate of photonitration in the presence of RDX/PETN. As seen in Figure 10, for DHAs with ethyl or isopropyl substituents at the 9-position, the *N*-H analogues reacted faster the *N*-Me analogues. For DHAs with phenyl or methyl substituents in the 9-position, this trend was reversed and *N*-Me analogues displayed the fastest reaction rates. Moreover, *N*-arylation was found to significantly retard the rate of photonitration.

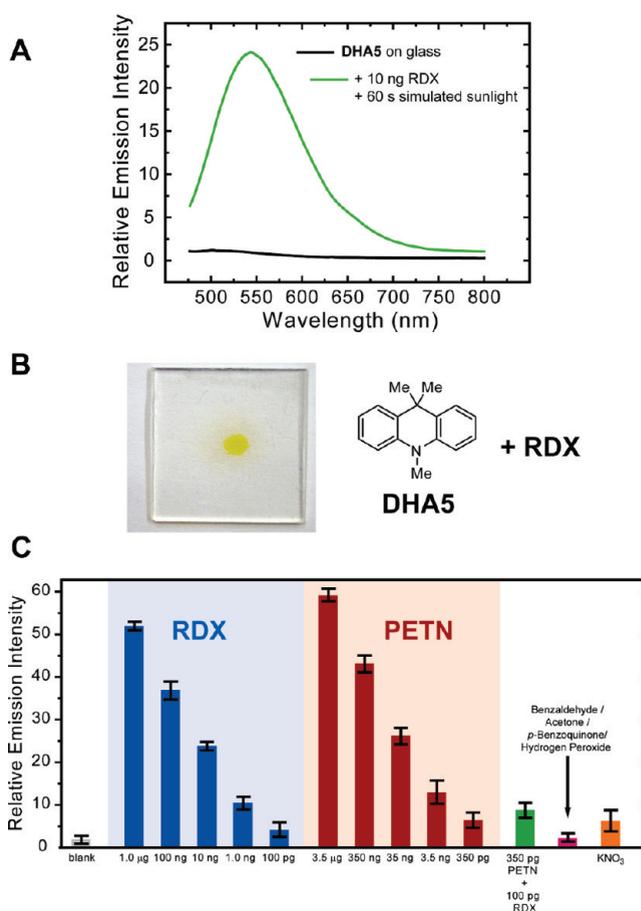

**Figure 11.** Comparison of the rates of nitration of **DHA5** vs **DMA** in the presence of (A) **RDX** or (B) **PETN**.

Lastly, the rate of formation of nitrated DHAs was compared to the formation of **DMNA** from **DMA**. As seen in Figure 11, the reactivity of **DHA5**, which displayed the fastest rate of nitration among **DHA1-18**, is comparable to that of **DMA**.

**Solid-State RDX/PETN Detection.** On the basis of the previously detailed rates of nitration of **DHA1-18** by the photofragmentation products of **RDX** and **PETN**, we initially chose to focus on **DHA5**, **DHA8**, **DHA11**, and **DHA13** as potential indicators for **RDX** and **PETN**, as they displayed the fastest rates of reaction. Between these four DHAs, **DHA5** and **DHA8** were favored because their nitrated products displayed high fluorescence quantum yields. We chose to use **DHA5** to demonstrate detection of **RDX/PETN** in the solid state; however, similar results and detection limits were also obtained with **DHA8**.

In order to evaluate the utility of **DHA5** as a fluorescent indicator for **RDX** and **PETN**, the solid-state response of **DHA5** to **RDX** and **PETN** was investigated. For this study, glass slides coated with **DHA5** were prepared by dipcoating into  $8 \times 10^{-3}$  M solutions of the indicator in acetonitrile and air drying. **RDX** and **PETN** solutions of varying concentration were spotted onto the surface and the slides then irradiated with a solar simulator for no longer than 120 s.

As shown in Figure 12A, an acceptable turn-on emission signal at 540 nm was generated by 10 ng of **RDX** after 60 s of irradiation with a solar simulator. In addition to a fluorescence signal, the distinct yellow color of **27** could also be observed by eye, as shown in Figure 12B. The limits of detection of the **DHA5** chemosensor were estimated by spotting **RDX** or **PETN** solutions of varying concentrations onto the **DHA5**-coated slides and are shown in Figure 12C. In general, a greater emission signal at 540 nm was generated by **PETN** over **RDX**, possibly because **PETN** is more susceptible to photodegradation than **RDX**.

**Figure 12.** (A) Emission profile ( $\lambda_{\text{ex}}$  420 nm) of a glass slide coated with **DHA5** (black line) and the same slide after spotting with ca. 10 ng of **RDX** and irradiating with a solar simulator for 60 s (green line). (B) Picture of a glass slide coated with **DHA5**, spotted with ca. 10 ng **RDX** and exposed to simulated sunlight for 120 s. (C) Limits of solid-state detection of **RDX** and **PETN** as measured by monitoring the change in emission intensity at 540 nm upon exposure (60 s) to simulated sunlight. In the case of potassium nitrate, a concentrated solution (30 mM) in acetonitrile and long exposure times (600 s) were necessary to obtain the 8-fold increase shown.

Select interferents, such as ketones and aldehydes, did not produce a significant emission signal at 540 nm. Moreover, consistent with observations made during the synthesis of **D1**, hydrogen peroxide did not react readily with **DHA5** and most likely only formed a small quantity of the radical cation of **DHA5**, which is nonemissive and therefore did not produce any emission at 540 nm.

Aqueous potassium nitrate solutions of varying concentrations were also spotted onto the **DHA5**-coated glass slides in order to gauge the response of the **DHA5** indicator to nitrate contaminants. Consistent with previous observations, submicromolar solutions of potassium nitrate did not generate a significant emission signal at 540 nm after 1 h in either the absence of presence of simulated solar irradiation. Using a 30 mM solution of potassium nitrate, an approximately 8-fold increase in the emission intensity at 540 nm was observed after a 10 min exposure to simulated sunlight. However, given the high nitrate concentration and relatively long irradiation time necessary to effect this emission signal, interference from nitrates during **RDX/PETN** detection can, in theory, be surmounted.

Within experimental error, approximately 100 pg of RDX and PETN can be detected by the DHAS indicator under aerobic conditions by monitoring the emission intensity at 540 nm. In the presence of nitrate interferents, this detection limit is conservatively estimated as ca. 1 ng. These detection limits, although not low enough for the detection of equilibrium vapor, are competitive with present transportation security systems that make use of swipes to collect particles.

## CONCLUSIONS

We have found that the nitramine-containing explosive RDX and the nitroester-containing explosive PETN are susceptible to photofragmentation upon exposure to sunlight to produce reactive  $\text{NO}_x$  species, such as nitrogen dioxide and nitric acid. *N,N*-Dimethylaniline and 9,9-disubstituted 9,10-dihydroacridines (DHAs) are capable of being selectively nitrated by the reactive, electrophilic  $\text{NO}_x$  photofragmentation products of RDX and PETN. This nitration reaction proceeds rapidly and yields only one major, singly nitrated product. A roughly 25-fold increase in the emission signal at 550 nm is observed upon nitration of DHAs due to the generation of fluorescent donor–acceptor chromophores. By monitoring the emission intensity at ca. 550 nm, the presence of approximately 100 pg of RDX or PETN can be detected within 1 min by these indicators in the solid state upon exposure to sunlight. The photonitration reaction presented herein is a unique and selective detection mechanism for nitroester and nitramine explosives that is distinct from a previously reported photoreduction reaction to detect explosives. The rapid nitration of 9,9-diphenyl- or -dimethyl-substituted DHA chemosensors in the presence of RDX or PETN and the resulting strong, turn-on emission signal qualify these DHAs as cheap, impermanent indicators for the selective, standoff identification of nitroester and nitramine explosives.

## EXPERIMENTAL SECTION

**Materials, Instrumentation, and General Experimental Methods.** Synthetic manipulations that required an inert atmosphere (where noted) were carried out under argon using standard Schlenk techniques. All solvents were of reagent grade or better unless otherwise noted. All solvents used for photophysical experiments were of spectroscopic grade. Anhydrous tetrahydrofuran, diethyl ether, toluene, and dichloromethane were obtained from a dry solvent system. Spectroscopic-grade acetonitrile was degassed and stored over 4 Å sieves.  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra for all compounds were acquired in  $\text{CHCl}_3$  at 400 and 100 MHz, respectively. The chemical shift data are reported in units of  $\delta$  (ppm) relative to tetramethylsilane (TMS) and referenced with residual  $\text{CHCl}_3$ .  $^{19}\text{F}$  NMR spectra were recorded at 380 MHz. Trichlorofluoromethane was used as an external standard (0 ppm), and upfield shifts are reported as negative values. In some cases, signals associated with the  $\text{CF}_3$  groups and proximal quaternary centers were not reported in the  $^{13}\text{C}$  NMR spectra due to C–F coupling and low signal-to-noise ratios. High-resolution mass spectra (HRMS) were obtained using a peak-matching protocol to determine the mass and error range of the molecular ion, employing either electron impact or electrospray as the ionization technique. GC–MS (electron impact mass spectrometer) data were recorded in the temperature range of 100–350 °C under a vacuum of at least  $10^{-5}$  Torr. GC retention times are reported in minutes. X-ray crystal structures were determined with graphite-monochromated  $\text{Mo K}\alpha$  radiation ( $\lambda = 0.71073 \text{ \AA}$ ). All structures were solved by direct methods using SHELXS<sup>26</sup> and refined against F on all data by full-matrix least-squares with SHELXL-97. All non-hydrogen atoms

were refined anisotropically. All electrochemical measurements were made using a quasi-internal Ag wire reference electrode submerged in 0.01 M  $\text{AgNO}_3/0.1 \text{ M } n\text{-Bu}_4\text{NPF}_6$  in anhydrous MeCN. Typical CVs were recorded using a platinum button electrode as the working electrode and a platinum coil counter electrode. The ferrocene/ferrocenium ( $\text{Fc}/\text{Fc}^+$ ) redox couple was used as an external reference. Ultraviolet–vis absorption spectra were corrected for background signal with either a solvent-filled cuvette (solutions) or a blank microscope slide (films). Fluorescence spectra were measured using either right-angle (solutions) or front-face (22.5°) detection (thin films). Fluorescence quantum yields were determined by the optically dilute method<sup>27</sup> using quinine sulfate in 0.1 M  $\text{H}_2\text{SO}_4$  as a standard ( $\Phi = 0.53$ ) and were corrected for solvent refractive index and absorption differences at the excitation wavelength. Fluorescence lifetimes were measured via frequency modulation using a 365 nm laser diode as the light source and the modulation of POPOP as a calibration reference. For photolysis experiments,<sup>28</sup> solutions were irradiated under air at 313 nm using either: (1) the xenon lamp (450 W) from a fluorimeter, with the excitation slit set to 29.4 nm (the maximum value); (2) a 500 W Mercury Arc Lamp fitted with a 313 nm interference filter (or a 334 or 365 nm interference filter) and varying neutral density filters (0.5, 1.0, or 2.0 OD); or (3) a solar simulator equipped with a 450 W xenon arc lamp, with a spectral output of 1.3 suns under AM 1.5 conditions. The first two light sources were calibrated with a potassium ferric oxalate actinometer.<sup>29</sup> For each measurement, reaction progress was also monitored in the dark to ensure that there was no thermal contribution to the nitration of aromatic amines by RDX and PETN. Each photolysis experiment was performed in triplicate. *N*-Phenylanthranilic acid was esterified following a literature procedure.<sup>30</sup> RDX and PETN were obtained from K-9 training units, which consisted of RDX/PETN adsorbed onto sand. RDX and PETN were extracted from the sand with spectral grade acetonitrile and precipitated by the addition of DI water. The solids thus isolated were recrystallized three times from chloroform/acetonitrile and stored in the dark at  $-4 \text{ }^\circ\text{C}$ .

***N,N*-Dimethyl-4-nitroaniline (DMNA).** A mixture of 0.4 mL of DMA and 0.1 g of either RDX or PETN were dissolved in 3.0 mL of dry, degassed acetonitrile, and the solution was photolyzed with a xenon arc lamp at 313 nm for 60 min. The reaction mixture was sampled every 10 min to determine the GC yield of the DMNA product. Approximately 80% of DMNA (GC yield) was formed after 60 min of photolysis. The yellow DMNA was isolated by flash column chromatography using 50/50 hexanes/dichloromethane as an eluent:  $^1\text{H}$  NMR (400 MHz,  $\text{CHCl}_3$ )  $\delta$  3.11 (s, 6H), 6.59 (d,  $J = 8.2 \text{ Hz}$ , 2H), 8.09 (d,  $J = 8.2 \text{ Hz}$ , 2H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CHCl}_3$ )  $\delta$  40.2, 110.2, 126.0, 136.9, 154.3; HRMS (ESI) calcd for  $\text{C}_8\text{H}_{11}\text{N}_2\text{O}_2$  [ $\text{M} + \text{H}$ ]<sup>+</sup> 167.0815, found 167.0819; IR (KBr plate) 695 (s), 750 (s), 820 (s), 1067 (m), 1118 (m), 1232 (m), 1347 (m), 1383 (w), 1456 (s), 1483 (s), 1582 (s), 1615 (w), 2924 (m)  $\text{cm}^{-1}$ .

**General Procedure for the Synthesis of 9,9-Disubstituted 9,10-Dihydroacridines (DHA1-4).** A flame-dried Schlenk flask was charged with 1.0 g of methyl *N*-phenylanthranilate (14, 4.4 mmol) and 45 mL of dry, degassed  $\text{Et}_2\text{O}$  under argon and cooled to 0 °C in an ice bath. A 3.5 equiv portion of the appropriate Grignard reagent in  $\text{Et}_2\text{O}$  was added dropwise and the reaction mixture allowed to stir at room temperature under argon for 3 d. After the mixture was quenched with saturated ammonium chloride, the organic layer was separated, washed with brine and water, and dried over  $\text{MgSO}_4$  and the solvent evaporated under reduced pressure. The crude tertiary alcohol thus formed was carried on to the next step without purification. To the neat oil isolated from the previous step was added 1–2 mL of concentrated  $\text{H}_2\text{SO}_4$  under argon and the reaction stirred at room temperature for 1 h under argon. After dilution with 30 mL of DI  $\text{H}_2\text{O}$ , the reaction was poured into a 10% (v/v) aqueous ammoniacal solution and extracted with ether ( $5 \times 50 \text{ mL}$ ). The combined organic layers were washed with saturated

sodium bicarbonate, brine, and water and dried over  $\text{MgSO}_4$ , and the solvent was evaporated under reduced pressure. The residue was purified by flash column chromatography to yield the desired compound.

**9,9-Dimethyl-9,10-dihydroacridine (DHA1).** Synthesized using 3.0 M methylmagnesium bromide in  $\text{Et}_2\text{O}$  and purified by flash column chromatography using gradient elution, starting with 10% dichloromethane in hexanes and progressing to 50% dichloromethane in hexanes: 0.41 g (45%) of a white solid was isolated; mp 120 °C;  $^1\text{H}$  NMR (400 MHz,  $\text{CHCl}_3$ )  $\delta$  1.54 (s, 6H), 6.11 (s, 1H), 6.67 (dd,  $J = 0.8$  Hz, 7.6 Hz, 2H), 6.90 (m, 2H), 7.09 (m, 2H), 7.37 (d,  $J = 7.6$  Hz, 2H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CHCl}_3$ )  $\delta$  30.7, 36.4, 113.6, 120.8, 125.7, 126.9, 129.3, 138.6. HRMS (ESI) calc for  $\text{C}_{15}\text{H}_{15}\text{N}$   $[\text{M} + \text{H}]^+$  210.1277, found 210.1284. IR (KBr plate) 745 (s), 886 (m), 1037 (m), 1318 (m), 1452 (m), 1479 (s), 1507 (m), 1580 (m), 1606 (m), 2966 (m), 3359 (m)  $\text{cm}^{-1}$ .

**9,9-Diethyl-9,10-dihydroacridine (DHA2).** Synthesized using 3.0 M ethylmagnesium bromide in  $\text{Et}_2\text{O}$  and purified by flash column chromatography using hexanes as the eluent: 0.36 g (35%) of a clear oil was isolated;  $^1\text{H}$  NMR (400 MHz,  $\text{CHCl}_3$ )  $\delta$  0.91 (t,  $J = 7.6$  Hz, 3H), 0.97 (t,  $J = 7.6$  Hz, 3H), 2.24 (q,  $J = 7.6$  Hz, 2H), 2.35 (q,  $J = 7.6$  Hz, 2H), 5.74 (s, 1H), 6.90 (m, 3H), 7.06 (m, 5H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CHCl}_3$ )  $\delta$  13.0, 13.1, 13.9, 14.8, 24.3, 31.7, 115.9, 116.8, 118.2, 118.5, 120.3, 120.5, 121.0, 121.2, 123.0, 124.9, 127.4, 127.5, 129.5, 129.7, 130.1, 130.2, 134.3, 140.1, 140.3, 141.2, 143.5, 143.7; HRMS (ESI) calc for  $\text{C}_{17}\text{H}_{19}\text{N}$   $[\text{M} + \text{H}]^+$  238.1590, found 238.1591; IR (KBr plate) 692 (m), 745 (s), 1309 (m), 1451 (m), 1507 (s), 1575 (m), 1593 (s), 2871 (m), 2930 (m), 2965 (m), 3041 (m), 3403 (m)  $\text{cm}^{-1}$ .

**9,9-Diisopropyl-9,10-dihydroacridine (DHA3).** Synthesized using 2.0 M isopropylmagnesium chloride in  $\text{Et}_2\text{O}$  and purified by flash column chromatography using hexanes as the eluent: 0.19 g (17%) of a clear oil was isolated;  $^1\text{H}$  NMR (400 MHz,  $\text{CHCl}_3$ )  $\delta$  0.77 (d,  $J = 6.8$  Hz, 3H), 1.02 (d,  $J = 6.8$  Hz, 3H), 1.46 (s, 3H), 1.87 (s, 3H), 3.06 (septet,  $J = 6.8$  Hz, 1H), 5.75 (s, 1H), 6.88 (m, 5H), 7.20 (m, 4H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CHCl}_3$ )  $\delta$  19.7, 20.9, 22.4, 22.2, 30.6, 115.5, 118.6, 119.8, 121.2, 127.1, 129.5, 129.8, 130.0, 130.7, 136.8, 141.0, 143.5; HRMS (ESI) calc for  $\text{C}_{19}\text{H}_{24}\text{N}$   $[\text{M} + \text{H}]^+$  266.1903, found 266.1904; IR (KBr plate) 693 (s), 745 (s), 1079 (m), 1309 (s), 1450 (s), 1508 (s), 1576 (s), 1594 (s), 2961 (m), 3399 (s)  $\text{cm}^{-1}$ .

**9,9-Diphenyl-9,10-dihydroacridine (DHA4).** Synthesized using 3.0 M phenylmagnesium bromide in  $\text{Et}_2\text{O}$  and purified by flash column chromatography using gradient elution, starting with 10% dichloromethane in hexanes and progressing to 50% dichloromethane in hexanes: 0.83 g (57%) of a white solid was isolated; mp 230 °C;  $^1\text{H}$  NMR (400 MHz,  $\text{CHCl}_3$ )  $\delta$  6.25 (s, 1H), 6.86 (m, 9H), 7.16 (m, 8H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CHCl}_3$ )  $\delta$  30.1, 56.7, 113.5, 120.2, 125.6, 126.1, 126.2, 127.1, 127.4, 127.6, 127.6, 127.9, 128.5, 130.0, 130.2, 130.2, 139.7, 146.0, 149.3; HRMS (ESI) calc for  $\text{C}_{25}\text{H}_{19}\text{N}$   $[\text{M} + \text{H}]^+$  334.1590, found 334.1584; IR (KBr plate) 699 (m), 734 (m), 753 (m), 907 (m), 1315 (m), 1474 (s), 1604 (m), 3057 (w), 3393 (m)  $\text{cm}^{-1}$ .

**Methyl *N*-Methyl-*N*-phenylanthranilate (15).** A flame-dried two-neck round-bottom flask was charged with 8 g of *N*-phenylanthranilic acid (37.5 mmol), 0.3 mL of 15-crown-5, 300 mL of dry THF, and 100 mL of dimethoxyethane under argon. The solution was cooled to 0 °C in an ice bath, 5 g of a 60 wt % dispersion of NaH in mineral oil (3 g NaH, 125 mmol) was added to the reaction mixture in small portions under argon, and 15 mL dimethyl sulfate (19.99 g, 158 mmol) was added via syringe. After being stirred at room temperature for 5 d under argon, the reaction mixture was poured carefully onto 800 g of ice and extracted with  $\text{Et}_2\text{O}$  ( $5 \times 50$  mL). The organic layers were combined, washed thoroughly with saturated sodium bicarbonate ( $3 \times 25$  mL), brine, and water, and dried over  $\text{MgSO}_4$ , and the solvent was evaporated under reduced pressure. The resulting oil was purified by flash column chromatography using gradient elution, starting with 100% hexanes and progressing to 30% dichloromethane in hexanes to yield 7.2 g (80%)

of a yellow oil:  $^1\text{H}$  NMR (400 MHz,  $\text{CHCl}_3$ )  $\delta$  3.28 (s, 3H), 3.58 (s, 3H), 6.63 (dd,  $J = 8.8, 1.2$  Hz, 2H), 6.73 (td,  $J = 6, 1.2$  Hz, 1H), 7.16 (td,  $J = 7.2, 1.6$  Hz, 2H), 7.27 (m, 2H), 7.53 (td,  $J = 8, 1.6$  Hz, 1H), 7.79 (dd,  $J = 7.6, 1.6$  Hz, 1H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CHCl}_3$ )  $\delta$  40.5, 52.3, 114.4, 118.1, 125.4, 129.1, 129.2, 129.4, 131.6, 133.4, 148.3, 129.4, 167.7; HRMS (ESI) calc for  $\text{C}_{15}\text{H}_{15}\text{NO}_2$   $[\text{M} + \text{H}]^+$  242.1176, found 242.1170; IR (KBr plate) 2924 (s), 2853 (s), 1728 (m), 1594 (m), 1500 (m), 1454 (m), 1391 (w), 1253 (s), 1214 (s), 1062 (m), 1005 (m), 758 (m), 575 (m)  $\text{cm}^{-1}$ .

**General Procedure for the Synthesis of 9,9-Disubstituted 10-Methyl-9,10-dihydroacridines (DHA5–9).** A flame-dried Schlenk flask was charged with 1.0 g of methyl *N*-methyl-*N*-phenylanthranilate (15, 4.1 mmol) and 45 mL of dry, degassed  $\text{Et}_2\text{O}$  under argon and cooled to 0 °C in an ice bath. A 2.5 equiv portion of the appropriate Grignard reagent in  $\text{Et}_2\text{O}$  was added dropwise and the reaction allowed to stir at room temperature under argon for 3 d. After the reaction was quenched with saturated ammonium chloride, the organic layer was separated, washed with brine and water, and dried over  $\text{MgSO}_4$  and the solvent evaporated under reduced pressure. The crude tertiary alcohol thus formed was carried on to the next step without purification. To the neat oil isolated from the previous step was added 1–2 mL of concentrated  $\text{H}_2\text{SO}_4$  under argon and the reaction stirred at room temperature for 1 h under argon. After dilution with 30 mL of DI  $\text{H}_2\text{O}$  the reaction was poured into a 10% (v/v) aqueous ammoniacal solution and extracted with ether ( $5 \times 50$  mL). The combined organic layers were washed with saturated sodium bicarbonate, brine, and water and dried over  $\text{MgSO}_4$ , and the solvent was evaporated under reduced pressure. The residue was purified by flash column chromatography to yield the desired compound.

**9,9-Dimethyl-10-methyl-9,10-dihydroacridine (DHA5).** Synthesized using 3.0 M methylmagnesium bromide in  $\text{Et}_2\text{O}$  and purified by flash column chromatography using gradient elution, starting with 10% dichloromethane in hexanes and progressing to 50% dichloromethane in hexanes: 0.39 g (42%) of a light yellow solid was isolated; mp 93 °C;  $^1\text{H}$  NMR (400 MHz,  $\text{CHCl}_3$ )  $\delta$  1.52 (s, 6H), 3.43 (s, 3H), 6.96 (m, 4H), 7.21 (m, 2H), 7.38 (d,  $J = 1.6$  Hz, 2H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CHCl}_3$ )  $\delta$  27.4, 33.5, 36.7, 112.3, 120.8, 123.8, 126.8, 132.8, 142.4; HRMS (ESI) calc for  $\text{C}_{16}\text{H}_{17}\text{N}$   $[\text{M} + \text{H}]^+$  224.1434, found 224.1429; IR (KBr plate) 751 (s), 1046 (m), 1268 (s), 1340 (s), 1450 (s), 1470 (s), 1590 (s), 2900 (m), 2950 (s), 2980 (s), 3050 (m)  $\text{cm}^{-1}$ .

**9,9-Diethyl-10-methyl-9,10-dihydroacridine (DHA6).** Synthesized using 3.0 M ethylmagnesium bromide in  $\text{Et}_2\text{O}$  and purified by flash column chromatography using hexanes as the eluent. 0.31 g (30%) of a clear oil was isolated;  $^1\text{H}$  NMR (400 MHz,  $\text{CHCl}_3$ )  $\delta$  0.81 (t,  $J = 7.6$  Hz, 3H), 0.84 (t,  $J = 7.6$  Hz, 3H), 2.14 (q,  $J = 7.6$  Hz, 2H), 2.27 (q,  $J = 7.6$  Hz, 2H), 3.06 (s, 3H), 6.65 (m, 3H), 7.17 (m, 5H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CHCl}_3$ )  $\delta$  14.2 (2), 14.3, 22.5, 22.8, 23.2, 23.4, 29.6, 30.4, 31.0, 31.2, 31.7, 37.1, 39.4, 39.6, 114.0, 114.1, 117.2, 117.3, 125.5, 125.9, 127.8, 128.1, 128.2, 128.4, 128.7, 128.9, 130.5, 132.0, 132.5, 140.0, 140.1, 141.5, 143.4, 146.1, 147.0, 149.3, 149.5; HRMS (ESI) calc for  $\text{C}_{18}\text{H}_{21}\text{N}$   $[\text{M} + \text{H}]^+$  252.1747, found 252.1742; IR (KBr plate) 692 (s), (748 (s), 1342 (m), 1444 (m), 1487 (s), 1500 (s), 1568 (m), 1592 (s), 1602 (s), 2810 (m), 2870 (m), 2963 (m), 3024 (m)  $\text{cm}^{-1}$ .

**9,9-Diisopropyl-10-methyl-9,10-dihydroacridine (DHA7).** Synthesized using 2.0 M isopropylmagnesium chloride in  $\text{Et}_2\text{O}$  and purified by flash column chromatography using hexanes as the eluent: 0.19 g (17%) of a clear oil was isolated;  $^1\text{H}$  NMR (400 MHz,  $\text{CHCl}_3$ )  $\delta$  0.85 (d,  $J = 7.2$  Hz, 3H), 0.89 (d,  $J = 7.6$  Hz, 3H), 1.46 (s, 3H), 1.80 (s, 3H), 2.84 (septet,  $J = 7.2$  Hz, 1H), 3.03 (s, 3H), 6.74 (m, 3H), 6.98 (m, 1H), 7.13 (m, 5H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CHCl}_3$ )  $\delta$  21.6, 22.3, 23.8, 31.8, 39.0, 114.6, 117.4, 120.6, 121.4, 125.2, 127.4, 127.8, 128.0, 128.7, 129.4, 133.6, 140.0, 141.2, 147.2, 149.6; HRMS (ESI) calc for  $\text{C}_{20}\text{H}_{25}\text{N}$   $[\text{M} + \text{H}]^+$  280.2060, found 280.2058; IR (KBr plate) 748 (m), 1499 (m), 1601 (m), 2820 (m), 2910 (m) 3040 (m)  $\text{cm}^{-1}$ .

**9,9-Diphenyl-10-methyl-9,10-dihydroacridine (DHA8).**

Synthesized using 3.0 M phenylmagnesium bromide in Et<sub>2</sub>O and purified by flash column chromatography using gradient elution, starting with 10% dichloromethane in hexanes and progressing to 50% dichloromethane in hexanes: 0.79 g (55%) of a light yellow solid was isolated; mp 165–166 °C; <sup>1</sup>H NMR (400 MHz, CHCl<sub>3</sub>) δ 3.29 (s, 3H), 6.84 (m, 2H), 6.91 (m, 8H), 7.18 (m, 6H), 7.26 (m, 2H); <sup>13</sup>C NMR (100 MHz, CHCl<sub>3</sub>) δ 33.6, 57.3, 112.1, 120.0, 126.4, 127.4, 127.7, 130.1, 130.6, 131.4, 142.7, 146.2; HRMS (ESI) calc for C<sub>26</sub>H<sub>21</sub>N [M + H]<sup>+</sup> 348.1747, found 348.1732; IR (KBr plate) 638 (m), 699 (m), 733 (m), 755 (m), 1270 (m), 1348 (m), 1468 (s), 1590 (m), 1589 (m), 2815 (w), 2873 (w), 3056 (m) cm<sup>-1</sup>.

**9,9-Di-*n*-octyl-10-methyl-9,10-dihydroacridine (DHA9).**

Synthesized using 2.0 M octylmagnesium bromide in Et<sub>2</sub>O and purified by flash column chromatography using hexanes as the eluent: 0.7 g (40%) of a clear oil was isolated; <sup>1</sup>H NMR (400 MHz, CHCl<sub>3</sub>) δ 0.85 (t, J = 7.6 Hz, 3H), 0.88 (t, J = 7.2 Hz, 3H), 1.22 (bm, 22H), 2.08 (q, J = 7.2 Hz, 2H), 2.25 (t, J = 7.6 Hz, 2H), two overlapping singlets: δ 3.08, 3.10, total 3H, 5.35 (t, J = 7.6 Hz, 1H), 6.67 (m, 3H), 7.17 (m, 6H); <sup>13</sup>C NMR (100 MHz, CHCl<sub>3</sub>) δ 14.4, 22.9 (3), 28.3, 28.7, 29.0, 29.3, 29.5 (2), 29.6, 29.7 (2), 29.8, 30.0, 30.3, 31.1, 32.1 (2), 37.4, 39.4, 39.6, 114.0, 114.1, 117.2, 117.3, 125.5, 125.9, 128.0 (2), 128.2, 128.4, 128.6, 128.9, 130.7, 132.0, 132.5, 140.0, 140.7, 141.3, 143.4, 146.1, 146.9, 149.3, 149.5; HRMS (ESI) calc for C<sub>30</sub>H<sub>45</sub>N [M + H]<sup>+</sup> 420.3625, found 420.3613; IR (KBr plate) 692 (m), 747 (m), 1095 (w), 1342 (m), 1499 (s), 1592 (s), 1602 (s), 2854 (s), 2924 (s), 2955 (s), 3024 (w) cm<sup>-1</sup>.

**2-Bromo-*N*-methyl-*N*-phenylaniline (18).** A flame-dried two-neck round-bottom flask was charged with 2-bromo-*N*-phenylaniline (3 g, 12.2 mmol), 0.1 mL of 15-crown-5, 200 mL of dry THF, and 50 mL of dimethoxyethane under argon. The solution was cooled to 0 °C in an ice bath, 0.6 g of a 60 wt % dispersion of NaH in mineral oil (0.36 g NaH, 15 mmol) was added to the reaction mixture in small portions under argon, and 1.4 mL of dimethyl sulfate (1.89 g, 15 mmol) was added via syringe. After being refluxed for 20 h under argon, the reaction mixture was poured carefully onto 500 g of ice and extracted with Et<sub>2</sub>O (5 × 50 mL). The organic layers were combined, washed thoroughly with saturated sodium bicarbonate (3 × 25 mL), brine, and water, and dried over MgSO<sub>4</sub>, and the solvent was evaporated under reduced pressure. The resulting oil was purified by flash column chromatography using gradient elution, starting with 100% hexanes and progressing to 30% dichloromethane in hexanes to yield 2.5 g (80%) of a clear oil: <sup>1</sup>H NMR (400 MHz, CHCl<sub>3</sub>) δ 3.22 (s, 3H), 6.56 (d, J = 7.6 Hz, 2H), 6.75 (t, J = 7.6 Hz, 1H), 7.15 (m, 3H), 7.25 (dd, J = 8.0, 2.0 Hz, 1H), 7.32 (td, J = 7.6, 1.2 Hz, 1H), 7.66 (dd, J = 8.0, 1.6 Hz, 1H); <sup>13</sup>C NMR (100 MHz, CHCl<sub>3</sub>) δ 39.1, 113.5, 117.8, 124.4, 127.9, 128.4, 129.1, 129.2, 130.6, 134.3, 147.0, 148.7; HRMS (ESI) calcd for C<sub>13</sub>H<sub>12</sub>BrN [M + H]<sup>+</sup> 262.0226, found 262.0234; IR (KBr plate) 654 (s), 691 (s), 748 (s), 872 (s), 1139 (s), 1137 (s), 1273 (s), 1346 (s), 1438 (m), 1467 (s), 1499 (s), 1580 (s), 1601 (s), 2813 (m), 2824 (s), 3058 (m), 3089 (m) cm<sup>-1</sup>.

**9-Ethyl-9,10-dimethyl-9,10-dihydroacridine (DHA10).** A flame-dried two-necked flask was charged with 2-bromo-*N*-methyl-*N*-phenylaniline (1.0 g, 3.8 mmol) and 100 mL dry THF under argon and cooled to -78 °C in a dry ice-acetone bath. A 2.6 mL portion of a 1.6 M solution of *n*-BuLi in hexanes (4.16 mmol) was added dropwise over 5 min, and the reaction mixture stirred at -78 °C under argon for 1 h. Methyl ethyl ketone (0.302 g, 4.2 mmol) was added in one portion to the reaction mixture at -78 °C, and the reaction allowed to warm to room temperature and stirred overnight under argon. After being quenched with saturated ammonium chloride, the reaction was extracted with Et<sub>2</sub>O, the organic layers were combined, washed with brine and water, and dried over anhydrous MgSO<sub>4</sub>, and the solvent was evaporated under reduced pressure. To the neat residue thus obtained was added 2 mL of concentrated H<sub>2</sub>SO<sub>4</sub> under argon and the mixture stirred at room

temperature for 1 h under argon. After dilution with 30 mL of DI H<sub>2</sub>O, the reaction was extracted with Et<sub>2</sub>O (5 × 50 mL), the organic layers were combined, washed with brine and water and dried over anhydrous MgSO<sub>4</sub>, and the solvent was evaporated under reduced pressure. The residue was purified by flash column chromatography using hexanes as the eluent to yield 0.57 g (57%) of the desired compound as a clear oil: <sup>1</sup>H NMR (400 MHz, CHCl<sub>3</sub>) δ 1.66 (dd, J = 6.8, 0.8 Hz, 3H), 1.78 (t, J = 1.2 Hz, 3H), 3.10 (s, 3H), 5.49 (m, 1H), 6.66 (m, 3H), 7.18 (m, 6H); <sup>13</sup>C NMR (100 MHz, CHCl<sub>3</sub>) δ 14.2, 15.2, 16.5, 24.2, 39.2, 39.6, 113.8, 114.1, 117.1, 117.4, 122.4, 124.4, 125.7, 125.9, 128.0, 128.2, 128.5, 128.8, 128.9, 130.6, 131.5, 136.4, 140.4, 144.3, 145.8, 146.9, 149.2, 149.4; HRMS (ESI) calc for C<sub>17</sub>H<sub>19</sub>N [M + H]<sup>+</sup> 238.1590, found 238.1587; IR (KBr plate) 692 (m), 747 (m), 1345 (m), 1444 (m), 1499 (s), 1592 (s), 1602 (s), 2918 (m), 3024 (m) cm<sup>-1</sup>.

**9-Methyl-9-phenyl-10-methyl-9,10-dihydroacridine (DHA11).**

A flame-dried two-necked flask was charged with 2-bromo-*N*-methyl-*N*-phenylaniline (1.0 g, 3.8 mmol) and 100 mL of dry THF under argon and cooled to -78 °C in a dry ice-acetone bath. A 2.6 mL portion of a 1.6 M solution of *n*-BuLi in hexanes (4.16 mmol) was added dropwise over 5 min and the reaction stirred at -78 °C under argon for 1 h. Acetophenone (0.49 mL, 0.51 g, 4.2 mmol) was added in one portion under argon at -78 °C, and the reaction allowed to warm to room temperature and stirred overnight under argon. After being quenched with saturated ammonium chloride, the reaction mixture was extracted with Et<sub>2</sub>O, the organic layers were combined, washed with brine and water, and dried over anhydrous MgSO<sub>4</sub>, and the solvent evaporated under reduced pressure. To the neat residue thus obtained was added 2 mL of concentrated H<sub>2</sub>SO<sub>4</sub> under argon and the mixture stirred at room temperature for 1 h under argon. After dilution with 30 mL of DI H<sub>2</sub>O, the reaction mixture was extracted with Et<sub>2</sub>O (5 × 50 mL), the organic layers were combined, washed with brine, and water, and dried over anhydrous MgSO<sub>4</sub>, and the solvent was evaporated under reduced pressure. The desired product was purified by flash column chromatography using gradient elution, starting with 20% dichloromethane in hexanes and progressing to 50% dichloromethane in hexanes to yield 0.55 g (50%) of a light yellow solid: mp 184 °C; <sup>1</sup>H NMR (400 MHz, CHCl<sub>3</sub>) δ 1.83 (s, 3H), 3.37 (s, 3H), 6.93 (m, 6H), 7.24 (m, 8H); <sup>13</sup>C NMR (100 MHz, CHCl<sub>3</sub>) δ 27.4, 28.2, 31.2, 33.6, 112.1 (2), 112.3, 113.7, 113.9, 116.9, 120.0, 120.4, 120.8, 123.8, 126.2, 126.4, 126.76, 126.7, 127.1, 127.38, 127.5, 127.7, 127.8, 127.9, 128.0, 128.5, 128.7, 128.8, 128.9, 130.1, 130.5, 131.4, 132.5, 142.0, 142.7, 146.2, 148.9; HRMS (ESI) calc for C<sub>21</sub>H<sub>19</sub>N [M + H]<sup>+</sup> 286.1590, found 286.1590; IR (KBr plate) 650 (m), 699 (m), 743 (m), 798 (m), 1290 (m), 1353 (m), 1468 (s), 1595 (m), 1631 (m), 2803 (w), 2898 (w), 3042 (m) cm<sup>-1</sup>.

**9-Isopropyl-9,10-dimethyl-9,10-dihydroacridine (DHA12).**

A flame-dried two-necked flask was charged with 2-bromo-*N*-methyl-*N*-phenylaniline (1.0 g, 3.8 mmol) and 100 mL of dry THF under argon and cooled to -78 °C in a dry ice-acetone bath. A 2.6 mL portion of a 1.6 M solution of *n*-BuLi in hexanes (4.16 mmol) was added dropwise over 5 min and the reaction stirred at -78 °C under argon for 1 h. Isopropyl methyl ketone (0.361 g, 4.2 mmol) was added in one portion to the reaction mixture at -78 °C and the reaction allowed to warm to room temperature and stirred overnight under argon. After being quenched with saturated ammonium chloride, the reaction mixture was extracted with Et<sub>2</sub>O, the organic layers were combined, washed with brine and water, and dried over anhydrous MgSO<sub>4</sub>, and the solvent was evaporated under reduced pressure. To the neat residue thus obtained was added 2 mL of concentrated H<sub>2</sub>SO<sub>4</sub> under argon and the mixture stirred at room temperature for 1 h under argon. After dilution with 30 mL of DI H<sub>2</sub>O, the reaction was extracted with Et<sub>2</sub>O (5 × 50 mL), the organic layers were combined, washed with brine, and water, and dried over anhydrous MgSO<sub>4</sub>, and the solvent was evaporated under reduced pressure. The residue was purified by flash column chromatography

using hexanes as the eluent to yield 0.62 g (60%) of the desired compound as a clear oil:  $^1\text{H}$  NMR (400 MHz,  $\text{CHCl}_3$ )  $\delta$  1.51 (s, 3H), 1.64 (s, 3H), 1.70 (s, 3H), 3.04 (s, 3H), 6.64 (m, 3H), 7.12 (m, 6H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CHCl}_3$ )  $\delta$  21.5, 22.2, 23.8, 31.8, 39.0, 114.6, 117.4, 120.6, 121.4, 125.1, 127.4, 127.8, 128.0, 128.7, 129.3, 133.6, 140.0, 141.1, 147.2, 149.5; HRMS (ESI) calc for  $\text{C}_{18}\text{H}_{21}\text{N}$   $[\text{M}+\text{H}]^+$  252.1747, found 252.1742; IR (KBr plate) 692 (m), 747 (s), 1137 (m), 1342 (m), 1443 (m), 1486 (s), 1499 (s), 1591 (s), 1601 (s), 2911 (m), 2984 (m)  $\text{cm}^{-1}$ .

#### 9-Ethyl-9-phenyl-10-methyl-9,10-dihydroacridine (DHA13).

A flame-dried two-necked flask was charged with 2-bromo-*N*-methyl-*N*-phenylaniline (1.0 g, 3.8 mmol) and 100 mL of dry THF under argon and cooled to  $-78^\circ\text{C}$  in a dry ice–acetone bath. A 2.6 mL portion of a 1.6 M solution of *n*-BuLi in hexanes (4.16 mmol) was added dropwise over 5 min and the reaction mixture stirred at  $-78^\circ\text{C}$  under argon for 1 h. Propiophenone (0.56 mL, 0.56 g, 4.2 mmol) was added in one portion to the reaction mixture under argon at  $-78^\circ\text{C}$  and the reaction allowed to warm to room temperature and stirred overnight under argon. After quenching with saturated ammonium chloride, the reaction was extracted with  $\text{Et}_2\text{O}$ , the organic layers were combined, washed with brine and water, and dried over anhydrous  $\text{MgSO}_4$ , and the solvent was evaporated under reduced pressure. To the neat residue thus obtained was added 2 mL of concentrated  $\text{H}_2\text{SO}_4$  under argon and the mixture stirred at room temperature for 1 h under argon. After dilution with 30 mL of DI  $\text{H}_2\text{O}$ , the reaction was extracted with  $\text{Et}_2\text{O}$  ( $5 \times 50$  mL), the organic layers were combined, washed with brine and water, and dried over anhydrous  $\text{MgSO}_4$ , and the solvent was evaporated under reduced pressure. The desired product was purified by flash column chromatography using 10% dichloromethane in hexanes as the eluent to yield 0.62 g (55%) of a light yellow oil:  $^1\text{H}$  NMR (400 MHz,  $\text{CHCl}_3$ )  $\delta$  0.74 (t,  $J = 7.2$  Hz, 3H), 2.22 (q,  $J = 7.2$  Hz, 2H), 3.38 (s, 3H), 6.75 (m, 4H), 6.89 (m, 2H), 7.17 (m, 3H), 7.27 (m, 4H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CHCl}_3$ )  $\delta$  9.7, 33.8, 34.6, 50.5, 111.9, 113.1, 113.8, 114.0, 116.9, 119.9, 125.4, 125.6, 125.9, 126.4, 126.5, 126.6, 126.7, 127.0, 127.3, 127.5, 127.8, 127.9, 128.2, 128.3, 128.8, 128.9, 129.2, 129.4, 129.6, 130.2, 132.9, 138.7, 141.3, 142.0, 143.5, 147.3, 148.5, 149.5; HRMS (EI) calcd for  $\text{C}_{22}\text{H}_{21}\text{N}$   $[\text{M}]^+$  299.1669, found 299.1673; IR (KBr plate) 633 (m), 693 (s), 747 (s), 1032 (w), 1260 (w), 1349 (m), 1448 (m), 1499 (s), 1575 (m), 1590 (s), 1601 (s), 2927 (m), 3024 (m)  $\text{cm}^{-1}$ .

#### 10-Methyl-10H-spiro[acridine-9,1'-cyclohexane] (DHA14).

A flame-dried two-necked flask was charged with 2-bromo-*N*-methyl-*N*-phenylaniline (1.0 g, 3.8 mmol) and 100 mL of dry THF under argon and cooled to  $-78^\circ\text{C}$  in a dry ice–acetone bath. A 2.6 mL portion of a 1.6 M solution of *n*-BuLi in hexanes (4.16 mmol) was added dropwise over 5 min and the reaction stirred at  $-78^\circ\text{C}$  under argon for 1 h. Cyclohexanone (0.43 mL, 0.412 g, 4.2 mmol) was added in one portion to the reaction mixture at  $-78^\circ\text{C}$  and the reaction allowed to warm to room temperature and stirred overnight under argon. After being quenched with saturated ammonium chloride, the reaction mixture was extracted with  $\text{Et}_2\text{O}$ , the organic layers were combined, washed with brine and water, and dried over anhydrous  $\text{MgSO}_4$ , and the solvent was evaporated under reduced pressure. To the neat residue thus obtained was added 2 mL of concentrated  $\text{H}_2\text{SO}_4$  under argon and the mixture stirred at room temperature for 1 h under argon. After dilution with 30 mL of DI  $\text{H}_2\text{O}$ , the reaction was extracted with  $\text{Et}_2\text{O}$  ( $5 \times 50$  mL), the organic layers were combined, washed with brine and water, and dried over anhydrous  $\text{MgSO}_4$ , and the solvent was evaporated under reduced pressure. The residue was purified by flash column chromatography using hexanes as the eluent to yield 0.3 g (30%) of the desired compound as a clear oil:  $^1\text{H}$  NMR (400 MHz,  $\text{CHCl}_3$ )  $\delta$  1.53 (m, 4H), 2.10 (m, 4H), 3.12 (s, 3H), 5.65 (m, 1H), 6.66 (m, 3H), 7.18 (m, 6H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CHCl}_3$ )  $\delta$  22.0, 23.0, 25.6, 28.2, 39.2, 113.7, 116.9, 125.6, 126.3, 127.7, 128.2, 128.5, 130.3, 137.9, 142.8, 145.6, 149.0; HRMS (ESI) calcd for  $\text{C}_{19}\text{H}_{21}\text{N}$   $[\text{M} + \text{H}]^+$  264.1747, found 264.1758;

IR (KBr plate) 693 (m), 747(m), 1069 (s), 1155 (m), 1263 (m), 1345 (m), 1499 (s), 1602(s), 2853 (m), 2921 (s)  $\text{cm}^{-1}$ .

#### 1,1,1,3,3,3-Hexafluoro-2-(2-(methyl(phenyl)amino)phenyl)propan-2-ol (21).

A flame-dried two-necked flask equipped with a dry ice/acetone condenser was charged with 2-bromo-*N*-methyl-*N*-phenylaniline (1.0 g, 3.8 mmol) and 100 mL dry THF under argon and cooled to  $-78^\circ\text{C}$  in a dry ice–acetone bath. A 2.6 mL portion of a 1.6 M solution of *n*-BuLi in hexanes (4.16 mmol) was added dropwise over 5 min and the reaction stirred at  $-78^\circ\text{C}$  under argon for 1 h. Making sure that the dry ice/acetone condenser remained filled, anhydrous hexafluoroacetone (HFA) gas was bubbled into the reaction flask at  $-78^\circ\text{C}$  under a positive pressure of argon for a total duration of 3 min; the pressure reading on the HFA tank was noted to be 22 psi. The reaction was allowed to warm to room temperature and the HFA allowed to reflux for an additional 3 h (making sure the dry ice/acetone condenser remained full for the duration) after which the excess HFA was removed by bubbling through a saturated KOH solution for 1 h. The reaction was quenched with saturated ammonium chloride and extracted with  $\text{Et}_2\text{O}$  ( $3 \times 50$  mL). The organic layers were combined, washed with brine and water, and dried over  $\text{MgSO}_4$ , and the solvent was evaporated under reduced pressure. The residue was purified by flash column chromatography using 50% dichloromethane in hexanes as the eluent to yield 1.1 g (80%) of the desired compound as a white crystalline solid after drying in vacuo for 3d:  $^1\text{H}$  NMR (400 MHz,  $\text{CHCl}_3$ )  $\delta$  3.08 (s, 3H), 6.87 (dd,  $J = 8.0$  Hz,  $J = 1.6$  Hz, 2H), 6.98 (m, 2H), 7.21 (m, 2H), 7.36 (m, 2H), 7.75 (d,  $J = 8.0$  Hz, 1H), 11.51 (s, 1H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CHCl}_3$ )  $\delta$  40.3, 80.3 (quintet), 115.0, 115.5, 118.8, 119.2 (2), 119.4, 120.6 121.5, 121.6, 122.0, 122.1, 122.9, 124.9 (3), 127.2, 127.7, 127.8, 127.9, 128.3, 128.9 (2), 129.0, 129.2, 129.3, 129.4, 129.6, 132.3, 149.2, 151.6.  $^{19}\text{F}$  NMR (380 MHz,  $\text{CHCl}_3$ )  $\delta$   $-76.4$ ,  $-75.1$ ; HRMS (ESI) calc for  $\text{C}_{16}\text{H}_{13}\text{F}_6\text{NO}$   $[\text{M} + \text{H}]^+$  350.0974, found 350.0961; IR (KBr plate) 479 (m), 693 (s), 709 (s), 754 (s), 848 (m), 936 (m), 954 (s), 968 (s), 1121 (s), 1147 (m), 1192 (s), 1260 (s), 1496 (s), 1577 (m), 1603 (m), 2719 (m), 2973 (m), 3066 (m), 3854 (broad)  $\text{cm}^{-1}$ .

#### 10-Methyl-9,9-bis(trifluoromethyl)-9,10-dihydroacridine (DHA15).

1,1,1,3,3,3-Hexafluoro-2-(2-(methyl(phenyl)amino)phenyl)propan-2-ol (0.2 g, 0.57 mmol) was dissolved in 15 mL of  $\text{POCl}_3$  and the solution refluxed under argon for 3 d. Excess  $\text{POCl}_3$  was distilled off using a short path distillation head, the residue was dissolved in  $\text{CHCl}_3$  and poured into a 10% (v/v) aqueous ammoniacal solution, and the biphasic system was stirred at room temperature for 1 h. The organic layer was separated and the aqueous layer extracted with  $\text{Et}_2\text{O}$  ( $3 \times 50$  mL). The organic layers were combined, washed with brine and water, and dried over  $\text{MgSO}_4$ , and the solvent was evaporated under reduced pressure. The residue was purified by flash column chromatography using 10% dichloromethane in hexanes as the eluent to yield 0.15 g (80%) of the desired compound as a light-blue oil:  $^1\text{H}$  NMR (400 MHz,  $\text{CHCl}_3$ )  $\delta$  3.46 (s, 3H), 7.00 (m, 4H), 7.42 (m, 2H), 7.89 (m, 2H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CHCl}_3$ )  $\delta$  29.8, 35.1, 111.8, 114.7, 120.3, 130.3 (quintet), 130.7, 141.8;  $^{19}\text{F}$  NMR (380 MHz,  $\text{CHCl}_3$ )  $\delta$   $-65.9$ ; HRMS (EI) calcd for  $\text{C}_{16}\text{H}_{11}\text{F}_6\text{N}$   $[\text{M}]^+$  332.0868, found 332.0874; IR (KBr plate) 479 (m), 693 (s), 709 (s), 758 (s), 848 (m), 954 (s), 1116 (s), 1163 (m), 1192 (s), 1260 (s), 1489 (s), 1573 (m), 1594 (m), 2840 (m), 2972 (m), 3054 (m)  $\text{cm}^{-1}$ .

**Methyl *N*-(*p*-Tolyl)-*N*-phenylanthranilate (22).** A flame-dried Schlenk flask was charged with 14 (5 g, 22 mmol), 4-bromotoluene (3 mL, 4.17 g, 24 mmol), copper powder (1.56 g, 24 mmol), copper(I) iodide (100 mg), potassium carbonate (3.3 g, 24 mmol), and 5 mL of hexyl ether under argon. The resulting mixture was heated to  $190^\circ\text{C}$  in a sand bath for 24 h. Upon cooling to room temperature, the reaction mixture was diluted with dichloromethane and passed through a Celite plug, and the solvents were evaporated under reduced pressure. The residual oil thus obtained was purified by flash column chromatography (30% dichloromethane in hexanes) to yield 5.2 g (75%) of an off-white

solid: mp 110–111 °C;  $^1\text{H}$  NMR (400 MHz,  $\text{CHCl}_3$ )  $\delta$  2.28 (s, 3H), 3.42 (s, 3H), 6.91 (m, 7H), 7.15 (m, 4H), 7.39 (t,  $J = 7.6$  Hz, 1H), 7.66 (d,  $J = 7.6$  Hz, 1H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CHCl}_3$ )  $\delta$  20.7, 51.7, 121.6, 122.0, 123.5, 123.8, 128.5, 128.7, 128.8, 129.6, 131.1, 132.1, 132.5, 145.1, 146.7, 148.0, 167.9; HRMS (EI) calc for  $\text{C}_{21}\text{H}_{19}\text{NO}_2$   $[\text{M} + \text{H}]^+$  318.1489, found 318.1481; IR (KBr plate) 693 (m), 713 (m), 753 (m), 813 (m), 1085 (m), 1125 (m), 1244 (s), 1271 (s), 1289 (s), 1320 (s), 1448 (s), 1492 (s), 1508 (s), 1594 (s), 1722 (s), 2947 (m), 3026 (m)  $\text{cm}^{-1}$ .

**9,9-Dimethyl-10-(*p*-tolyl)-9,10-dihydroacridine (DHA16) and 2,9,9-Trimethyl-10-phenyl-9,10-dihydroacridine (DHA17).**

A flame-dried Schlenk flask was charged with 1.0 g of methyl *N*-(*p*-tolyl)-*N*-phenylanthranilate (**22**, 3.1 mmol) and 45 mL of dry, degassed  $\text{Et}_2\text{O}$  under argon and cooled to 0 °C in an ice bath. A 2.5 equiv portion of 3.0 M methyl magnesium bromide in  $\text{Et}_2\text{O}$  (2.7 mL) was added dropwise and the reaction allowed to stir at room temperature under argon for 3 d. After the mixture was quenched with saturated ammonium chloride, the organic layer was separated, washed with brine and water, and dried over  $\text{MgSO}_4$  and the solvent evaporated under reduced pressure. The crude tertiary alcohol thus formed was carried on to the next step without purification. To the neat oil isolated from the previous step was added 1–2 mL of concentrated  $\text{H}_2\text{SO}_4$  under argon and the reaction stirred at room temperature for 1 h under argon. After dilution with 30 mL of DI  $\text{H}_2\text{O}$  the reaction mixture was poured into a 10% (v/v) aqueous ammoniacal solution and extracted with ether (5  $\times$  50 mL). The combined organic layers were washed with saturated sodium bicarbonate, brine, and water and dried over  $\text{MgSO}_4$ , and the solvent was evaporated under reduced pressure. The residue was purified by flash column using gradient elution, starting with 10% dichloromethane in hexanes and progressing to 50% dichloromethane in hexanes. A mixture of **DHA16** and **DHA17** was isolated as white solid: 0.52 g (55%). **DHA16** and **DHA17** could not be separated from each other: mp 100–102 °C;  $^1\text{H}$  NMR (400 MHz,  $\text{CHCl}_3$ )  $\delta$  1.66 (s, 9H), 2.27 (s, 3H), 2.46 (s, 3H), 6.13 (d,  $J = 8.4$  Hz, 1H), 6.22 (dd,  $J = 1.2, 8.0$  Hz, 1H), 6.26 (dd,  $J = 1.2$  Hz, 8.0 Hz, 1H), 6.74 (dd,  $J = 1.2, 8.0$  Hz, 1H), 6.92 (m, 5H), 7.18 (d,  $J = 8.4$  Hz, 2 H), 7.30 (d,  $J = 8.4$  Hz, 2H), 7.43 (m, 5H), 7.59 (m, 2H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CHCl}_3$ )  $\delta$  21.0, 21.6, 31.5, 31.6, 35.0, 36.2, 114.1, 114.3, 114.3, 120.4, 120.6, 125.4, 125.5, 126.1, 126.5, 126.6, 127.2, 128.4, 129.8, 130.1, 130.1, 130.2, 131.1, 131.2, 131.6, 131.8, 138.2, 138.7, 139.0, 141.3, 141.7; HRMS (ESI) calc for  $\text{C}_{22}\text{H}_{21}\text{N}$   $[\text{M} + \text{H}]^+$  300.1747, found 300.1756; IR (KBr plate) 745 (s), 886 (m), 1037 (m), 1318 (m), 1452 (m), 1479 (s), 1507 (m), 1580 (m), 1606 (m), 2966 (m)  $\text{cm}^{-1}$ .

**Methyl *N*-(2-Mesityl)-*N*-phenylanthranilate (**24**).** A flame-dried Schlenk flask was charged with **14** (5 g, 22 mmol), 2-bromomesitylene (3.67 mL, 4.77 g, 24 mmol), copper powder (1.56 g, 24 mmol), copper(I) iodide (100 mg), potassium carbonate (3.3 g, 24 mmol), and 5 mL of hexyl ether under argon. The resulting mixture was heated to 190 °C in a sand bath for 24 h. Upon cooling to room temperature, the reaction mixture was diluted with dichloromethane and passed through a Celite plug, and the solvents were evaporated under reduced pressure. The residual oil thus obtained was purified by flash column chromatography (30% dichloromethane in hexanes) to yield 4.18 g (55%) of an off-white solid: mp 90 °C;  $^1\text{H}$  NMR (400 MHz,  $\text{CHCl}_3$ )  $\delta$  2.03 (s, 6H), 2.30 (s, 3H), 3.26 (s, 3H), 6.65 (dd,  $J = 0.8$  Hz, 8.4 Hz, 1H), 6.81 (m, 3H), 6.93 (m, 3H), 7.11 (m, 2H), 7.21 (m, 1H), 7.60 (dd,  $J = 1.6, 7.6$  Hz, 1H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CHCl}_3$ )  $\delta$  19.0, 21.2, 51.5, 114.2, 117.3, 119.4, 121.1, 121.3, 122.5, 122.7, 123.2, 129.0, 129.3, 129.3, 129.6, 130.3, 130.5, 131.4, 131.9, 132.7, 134.3, 136.4, 136.9, 137.8, 138.1, 140.9, 145.0, 148.4, 168.9; HRMS (EI) calc for  $\text{C}_{23}\text{H}_{23}\text{NO}_2$   $[\text{M} + \text{H}]^+$  346.1802, found 346.1804; IR (KBr plate) 741 (m), 756 (m), 1238 (m), 1319 (m), 1448 (s), 1483 (s), 1593 (s), 1719 (s), 2857 (m), 2918 (m), 2948 (m), 3026 (m)  $\text{cm}^{-1}$ .

**9,9-Dimethyl-10-(2-mesityl)-9,10-dihydroacridine (DHA18).** A flame-dried Schlenk flask was charged with 1.0 g of methyl *N*-(2-

mesityl)-*N*-phenylanthranilate (**24**, 2.9 mmol) and 45 mL of dry, degassed  $\text{Et}_2\text{O}$  under argon and cooled to 0 °C in an ice bath. A 2.5 equiv portion of 3.0 M methylmagnesium bromide in  $\text{Et}_2\text{O}$  (2.4 mL) was added dropwise and the reaction allowed to stir at room temperature under argon for 3 d. After the mixture was quenched with saturated ammonium chloride, the organic layer was separated, washed with brine and water, and dried over  $\text{MgSO}_4$  and the solvent evaporated under reduced pressure. The crude tertiary alcohol thus formed was carried on to the next step without purification. To the neat oil isolated from the previous step was added 1–2 mL of concentrated  $\text{H}_2\text{SO}_4$  under argon and the reaction stirred at room temperature for 1 h under argon. After dilution with 30 mL of DI  $\text{H}_2\text{O}$ , the reaction was poured into a 10% (v/v) aqueous ammoniacal solution and extracted with ether (5  $\times$  50 mL). The combined organic layers were washed with saturated sodium bicarbonate, brine, and water and dried over  $\text{MgSO}_4$ , and the solvent was evaporated under reduced pressure. The residue was purified by flash column using gradient elution, starting with 10% dichloromethane in hexanes and progressing to 50% dichloromethane in hexanes. A white solid was thus isolated: 0.57 g (60%); mp 85 °C;  $^1\text{H}$  NMR (400 MHz,  $\text{CHCl}_3$ )  $\delta$  1.69 (s, 6H), 1.96 (s, 6H), 2.37 (s, 3H), 6.07 (dd,  $J = 1.6, 8.4$  Hz, 2H), 6.90 (m, 4H), 7.06 (s, 2H), 7.44 (dd,  $J = 1.6, 7.6$  Hz, 2H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CHCl}_3$ )  $\delta$  18.0, 20.2, 21.4, 33.5, 36.1, 112.7, 119.8, 120.4, 120.7, 126.3, 127.2, 128.6, 128.6, 129.3, 129.7, 130.4, 135.2, 138.1, 138.5, 138.7; HRMS (ESI) calc for  $\text{C}_{22}\text{H}_{21}\text{N}$   $[\text{M} + \text{H}]^+$  300.1747, found 300.1756; IR (KBr plate) 745 (s), 886 (m), 1315 (m), 1484 (s), 1507 (m), 1580 (m), 1606 (m), 2966 (m)  $\text{cm}^{-1}$ .

**10,10'-Dimethyl-9,9,9',9'-tetraphenyl-9,9',10,10'-tetrahydro-2,2'-biacridine (D1).** A flame-dried Schlenk flask was charged with **DHA8** (1.0 g, 2.8 mmol) and 10 mL of dry dichloromethane under argon. Triethylxonium hexachloroantimonate (1.26 g, 2.8 mmol) was added to this solution in one portion under argon. The reaction was stirred at room temperature for 12 h. A 10% aqueous solution of sodium thiosulfate was then added, the organic layer separated, washed with brine and water, and dried over  $\text{MgSO}_4$ , and the solvent evaporated under reduced pressure. The residue was purified by flash column using 50% dichloromethane in hexanes as eluent. A faint-yellow solid was thus isolated: 0.40 g (40%); mp 340 °C dec;  $^1\text{H}$  NMR (400 MHz,  $\text{CHCl}_3$ )  $\delta$  3.27 (s, 6H), 6.88 (m, 18H), 7.17 (m, 16H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CHCl}_3$ )  $\delta$  33.6, 57.4, 112.0, 112.4, 120.0, 125.3, 125.9, 126.3, 126.5, 127.4, 127.5, 127.7, 127.9, 128.3, 128.7, 130.2, 130.3, 130.5, 131.3, 131.8, 132.7, 141.5, 142.7, 146.0; HRMS (ESI) calc for  $\text{C}_{52}\text{H}_{41}\text{N}_2$   $[\text{M} + \text{H}]^+$  693.3264, found 693.3267; IR (KBr plate) 638 (m), 697 (m), 733 (m), 755 (m), 1270 (m), 1357 (m), 1463 (s), 1590 (m), 1589 (m), 2815 (w), 2873 (w), 3056 (m)  $\text{cm}^{-1}$ .

**9,9-Dimethyl-2-nitro-9,10-dihydroacridine (26).** A mixture of 0.5 g of **DHA1** (2.3 mmol) and 0.8 g of either RDX or PETN was dissolved in 3.0 mL of dry, degassed acetonitrile and the solution photolyzed with a solar simulator (1.3 suns AM 1.5) for 60 min. The reaction mixture was sampled every 10 min to determine the GC yield of the nitrated product. Approximately 80% of **26** (GC yield) was formed after 60 min of photolysis. Compound **26** was isolated by flash column chromatography using 50/50 hexanes/dichloromethane as an eluent:  $^1\text{H}$  NMR (400 MHz,  $\text{CHCl}_3$ )  $\delta$  1.62 (s, 6H), 6.64 (s, 1H), 6.69 (d,  $J = 8.8$  Hz, 1H), 6.75 (d,  $J = 8.8$  Hz, 1H), 7.03 (m, 1H), 7.15 (m, 1H), 7.40 (d,  $J = 7.6$  Hz, 1H), 8.02 (dd,  $J = 2.4, 8.8$  Hz, 1H), 8.30 (s, 1H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CHCl}_3$ )  $\delta$  30.7, 36.4, 113.6, 121.8, 126.7, 127.9, 130.2, 148.6; HRMS (ESI) calc for  $\text{C}_{15}\text{H}_{14}\text{N}_2\text{O}_2$   $[\text{M} + \text{H}]^+$  255.1128, found 255.1123; IR (KBr plate) 753 (s), 1053 (m), 1232 (m), 1347 (m), 1383 (w), 1456 (s), 1483 (s), 1582 (s), 1615 (w), 2924 (m)  $\text{cm}^{-1}$ .

**2-Nitro-9,9-diphenyl-9,10-dihydroacridine (28). Method A.** A mixture of 0.5 g of **DHA4** (1.5 mmol) and 0.8 g of either RDX or PETN were dissolved in 3.0 mL of dry, degassed acetonitrile and the solution photolyzed with a solar simulator (1.3 suns AM 1.5) for 60 min. The reaction mixture was sampled every 10 min to determine the GC

yield of the nitrated product. Approximately 80% of **28** (GC yield) was formed after 60 min of photolysis. Compound **28** was isolated by flash column chromatography using 50/50 hexanes/dichloromethane as an eluent:  $^1\text{H NMR}$  (400 MHz,  $\text{CHCl}_3$ )  $\delta$  7.12 (broad m, 16H), 8.02 (dd,  $J = 8.8, 2.2$  Hz, 1H), 8.30 (d,  $J = 2.2$  Hz, 1H);  $^{13}\text{C NMR}$  (100 MHz,  $\text{CHCl}_3$ )  $\delta$  56.7, 113.5, 120.2, 125.6, 126.1, 126.2, 127.1, 127.4, 127.5, 127.6, 127.9, 128.5, 131.0, 133.2, 137.3, 142.7, 146.0, 149.3; HRMS (ESI) calcd for  $\text{C}_{25}\text{H}_{19}\text{N}_2\text{O}_2$   $[\text{M} + \text{H}]^+$  379.1441, found 379.1447; IR (KBr plate) 699 (m), 762 (m), 907 (m), 1300 (m), 1330 (m), 1483 (s), 1529 (m), 1585 (s), 2922 (m), 3410 (m)  $\text{cm}^{-1}$ .

**2-Nitro-9,9-diphenyl-9,10-dihydroacridine (28). Method B.** Compound **28** was also synthesized by nitrating **DHA4**: A 25 mL round-bottom flask was charged with 0.5 g of **DHA4** (1.5 mmol) and 20 mL of dry dichloromethane under argon, and the solution was cooled to  $-78^\circ\text{C}$  in an acetone/dry ice bath. Approximately 0.2 g of 25%  $\text{HNO}_3$  on silica gel was then added to the solution and the reaction stirred at  $-78^\circ\text{C}$  for 1 h. Upon warming to room temperature, the reaction mixture was filtered and the solvent evaporated under reduced pressure. The residue was purified by flash column chromatography using 50/50 hexanes/dichloromethane as eluent. 40% of the mononitrated product (**28**, 40%) the dinitrated product (30%) were thus isolated.

**9,9-Dimethyl-2-nitro-10-(2-mesityl)-9,10-dihydroacridine (30).** A mixture of 0.5 g of **DHA18** (1.5 mmol) and 0.8 g of either RDX or PETN was dissolved in 3.0 mL dry, degassed acetonitrile and the solution photolyzed with a solar simulator (1.3 suns AM 1.5) for 60 min. The reaction mixture was sampled every 10 min to determine the GC yield of the nitrated product. Approximately 82% of **30** (GC yield) was formed after 60 min of photolysis. Compound **30** was isolated by flash column chromatography using 50/50 hexanes/dichloromethane as an eluent:  $^1\text{H NMR}$  (400 MHz,  $\text{CHCl}_3$ )  $\delta$  1.74 (s, 6H), 1.96 (s, 6H), 2.41 (s, 3H), 6.11 (d,  $J = 9.2$  Hz, 1H), 6.17 (dd,  $J = 2.8, 8.0$  Hz, 1H), 7.01 (m, 2H), 7.11 (s, 2H), 7.48 (m, 1H), 7.84 (dd,  $J = 2.4, 9.2$  Hz, 1H), 8.36 (d,  $J = 2.8$  Hz, 1H);  $^{13}\text{C NMR}$  (100 MHz,  $\text{CHCl}_3$ )  $\delta$  17.8, 21.4, 33.6, 36.3, 68.8, 112.4, 113.8, 122.8, 123.2, 123.9, 126.4, 127.7, 129.7, 130.0, 130.7, 134.1, 137.0, 137.5, 139.1, 141.0, 144.1; HRMS (ESI) calcd for  $\text{C}_{24}\text{H}_{25}\text{N}_2\text{O}_2$   $[\text{M} + \text{H}]^+$  373.1911, found 373.1913; IR (KBr plate) 750 (m), 848 (m), 1289 (s), 1306 (s), 1320 (s), 1475 (s), 1496 (s), 1592 (m), 1651 (s), 2918 (m), 2969 (m)  $\text{cm}^{-1}$ .

**9,9-Diethyl-2-nitro-9,10-dihydroacridine (31) and 9-Ethyl-9-vinyl-9,10-dihydroacridine (33).** A mixture of 0.5 g of **DHA2** (2.1 mmol) and 0.8 g of either RDX or PETN was dissolved in 3.0 mL of dry, degassed acetonitrile and the solution photolyzed with a solar simulator (1.3 suns AM 1.5) for 60 min. Compounds **31** and **33** were isolated by flash column chromatography using 50/50 hexanes/dichloromethane as an eluent. Compound **33** coeluted with unreacted **DHA2** and, therefore, could not be completely separated from **DHA2**. Compound **31**:  $^1\text{H NMR}$  (400 MHz,  $\text{CHCl}_3$ )  $\delta$  0.59 (t,  $J = 7.2$  Hz, 6H), 1.96 (quartet,  $J = 7.2$  Hz, 4H), 6.47 (s, 1H), 6.60 (d,  $J = 8.8$  Hz, 1H), 6.67 (d,  $J = 1.2$  Hz, 1H), 7.00 (m, 1H), 7.12 (m, 1H), 7.24 (m, 1H), 7.97 (d,  $J = 2.8$  Hz, 1H), 8.00 (s, 1H);  $^{13}\text{C NMR}$  (100 MHz,  $\text{CHCl}_3$ )  $\delta$  9.7, 38.8, 46.3, 112.9, 114.1, 122.8, 123.9, 124.1, 124.5, 125.2, 127.0, 127.4, 137.6, 145.2; HRMS (ESI) calcd for  $\text{C}_{17}\text{H}_{19}\text{N}_2\text{O}_2$   $[\text{M} + \text{H}]^+$  283.1441, found 283.1443; IR (KBr plate) 746 (m), 823 (m), 1242 (s), 1282 (s), 1294 (s), 1329 (m), 1462 (m), 1487 (s), 1530 (s), 1578 (s), 1609 (m), 2932 (m), 2968 (m), 3352 (s)  $\text{cm}^{-1}$ . Compound **33**:  $^1\text{H NMR}$  (400 MHz,  $\text{CHCl}_3$ )  $\delta$  0.91 (t,  $J = 7.6$  Hz, 3H), 0.97 (t,  $J = 7.6$  Hz, 3H), 1.48 (d,  $J = 6.8$  Hz, 2H), 1.79 (d,  $J = 6.8$  Hz, 3H), 2.24 (q,  $J = 7.6$  Hz, 2H), 2.35 (q,  $J = 7.6$  Hz, 2H), 5.48 (m, 1H), 5.72 (m, 1H), 5.74 (s, 1H), 6.90 (m, 4H), 7.06 (m, 5H);  $^{13}\text{C NMR}$  (100 MHz,  $\text{CHCl}_3$ )  $\delta$  13.0, 13.1, 13.9, 14.8, 24.3, 31.7, 115.9, 116.8, 118.2, 118.5, 120.3, 120.5, 121.0, 121.2, 123.0, 124.9, 127.4, 127.5, 129.5, 129.7, 130.1, 130.2, 134.3, 140.1, 140.3, 141.2, 143.5, 143.7; HRMS (ESI) calcd for  $\text{C}_{17}\text{H}_{17}\text{N}$   $[\text{M} + \text{H}]^+$  236.1434, found 236.1438; IR (KBr plate) 692 (m), 745 (m), 1309 (m), 1451 (m), 1506 (s), 1575 (m), 1594 (s), 2925 (m), 2963 (m), 3405 (m)  $\text{cm}^{-1}$ .
